There are a number of conceptual issues that complicate these positions. First, they imply that using genetic engineering to create an entirely new species would not be problematic whereas making slight alterations to the same species generally is. But this seems like a strange distinction to draw that does not capture the discomfort people have with genetic engineering. Second, species are not fixed entities but continuously change and evolve over time through natural mutations. So it is not clear why producing a genetically modified animal is more of a threat to the integrity of a species than naturally occurring mutations.

Moreover, as Paul Thompson (2008) has recently pointed out, even if we give some weight to the idea of species integrity, it is hard to see how that consideration could possibly trump the suffering of individual animals. If gene editing can reduce suffering, why should we prioritize the violation of an abstract notion of behavior engaged in by the typical member of a species over the very tangible benefits that occur in individual animals?

Welfare-Specific Arguments

In addition to the more general arguments that have been raised against genetic engineering, some proposals have been put forward

specifically to challenge the suggestion of improving welfare via genetic engineering.

A Slippery Slope for Human Welfare Enhancement

One concern with welfare engineering is that if we are willing to use genetic engineering to enhance the welfare of animals, similar reasoning could lead to the conclusion that we ought to do the same for human beings. Since it would clearly be wrong to genetically engineer humans, the argument suggests that there must be something wrong with the reasoning used to reach the conclusion in animals.

In response to this, various authors have pointed out disanalogies between the case of animals and humans. In particular, some have argued that the high value attached to humans' autonomy in modern bioethics would be threatened by welfare engineering in a way that is not relevant to other animals. Additionally, we have engaged in selective breeding of farm animals for thousands of years, but that has not led us down a slippery slope of selective breeding for humans, so why should we expect this technology to be different? And some deny that the idea of using genetic technology to enhance humans is itself intrinsically wrong.

Lack of Virtue

Virtue ethics, which analyzes how a virtuous person should behave, nicely captures one common way of objecting to welfare engineering. On this idea, there must be something flawed with our character if we would rather engineer animals to fit a bad environment instead of simply providing animals with an adequate environment (Thompson 2008). We would be, in effect, taking the path of least resistance and refusing to grapple with the seriousness of the initial problem created by modern agricultural systems. Moreover, one might suggest that we are only treating a "symptom" of a more widespread societal problem that overemphasizes profits and undervalues animal welfare.

Animal Integrity

One especially influential objection that arose in relation to genetic engineering is the notion of the

integrity of individual animals. Integrity refers to the wholeness or intactness of individual animals, and on this view "disenhancing" animals by depriving them of some natural aspect of their bodies or minds would be harming the animals. Though this critique needn't be limited to genetic engineering for welfare, one central article on the topic (Bovenkirk et al. 2001) specifically highlights the value of integrity in capturing the discomfort caused by the idea of animals engineered to be insentient lumps along the lines that Comstock described.

Bovenkirk et al.'s article pointed out some of the main challenges with the notion of integrity. First, they note that while the concept of integrity as wholeness sounds like it referring to an objective feature of animals, it actually is difficult to provide an objective definition that fits our moral intuitions. For example, some have suggested that docking a dog's tail for medical reasons is not a violation of integrity while docking the tail for esthetic reasons would be a violation, thus implying that identical changes may sometimes be violations of integrity and sometimes not. They also suggest that the notion of integrity is challenged by the fact that it is not clear how to provide a "gradation" of the concept that allows for variation in the seriousness of integrity, since integrity defined as wholeness seems like an all or nothing concept. Bovenkirk et al. suggest that similar problems exist for human integrity and environmental integrity, and they think that the fact that integrity aligns with people's intuitive discomfort with welfare engineering means that we should regard the concept as "flawed but workable" (2001, p. 20).

Summary

Genetic engineering has inspired a number of ideas about how to improve the welfare of animals, and recent technological advancements have greatly improved the efficiency and precision of genetic modification. Certain phenotypes achievable through genetic engineering, such as mastitis resistance or hornless cattle, are clearly beneficial to animal welfare whether achieved

quickly and precisely through genetic engineering or slowly through selective breeding. Other applications, such as eliminating the ability to feel pain, are less established in their benefit and practicality but theoretically have strong potential to improve welfare. Many ethical theories prominent in animal ethics would appear to be compatible with at least some proposed methods for welfare engineering. Nevertheless, the idea causes discomfort in some, and various scholars are developing alternative ethical frameworks that attempt to account for resistance to the idea.

Introduction

In the production of commodities, each producer of a particular good is a direct competitor to every

other producer of that same good, a situation known as the commodity trap. To avoid the commodity trap, where price is the only differentiating characteristic amongst similar products, farmers have long joined collective marketing arrangements, coming together to cooperatively differentiate their products from others', thereby increasing their incomes (Wolf 1944). Geographic indications (GIs), although not new, are an increasingly popular instrument of such collective marketing arrangements amongst producers and exporters of agri-food products. In 2009, there were more than 10,000 protected GIs in use globally whose estimated trade value exceeded US\$50 billion (Giovannucci et al. 2009). The vast majority of GIs are not well known and are often legally unprotected. It could be argued that the average consumer has consumed, knows of, or has seen GI products without realizing that those products are in fact GIs or what the GI represents. This entry will discuss the value, costs, and caveats of utilizing GIs as well as their current status in the global trading and legal environment. The practical considerations of pursuing and protecting a GI are also provided.

The discussion will demonstrate that pursuing and protecting a GI is not an easy, inexpensive, or short-term undertaking. This is particularly true for a GI originating in a developing country that is pursuing a "greenfield" export strategy in which the GI is entering a new export market (usually in a developed country) where it lacks profile, is relatively unknown amongst consumers, and therefore must "start from scratch" in terms of building awareness. Some studies exist that empirically show GIs earning price premiums but do not take into account the costs incurred to do so. Given that producers in developing countries have limited resources, pursuing GIs as an export strategy poses significant and high risks with uncertain outcomes; those limited resources may be better utilized elsewhere with less risk and more reliable results. Some developed country governments and NGOs are advocating the use of GIs as a strategy to improve agricultural incomes in developing countries without strong evidence of the efficacy of the strategy. The governments of developing countries considering

utilizing GIs as an agricultural and export development strategy should reconsider until empirical evidence conclusively illustrates that GIs increase producers' incomes. Essentially, GIs require further study utilizing empirical cost-benefit analysis before they can be recommended as an export strategy for developing country producers or as an agricultural development strategy for developing country governments.

What Is a GI?

Agri-food products with associated geographic names provide information to consumers. While an indication of the source (i.e. Product of Canada) informs consumers of a product's place of origin, a GI imparts further information regarding specific quality characteristics of the product due to its geographic source and grants exclusive rights to producers to market their designated products from a specified geographic area. Giovannucci et al. (2009) describe a GI as a concept that:

Identifies a good as originating in a delimited territory or region where a noted quality, reputation or other characteristic of the good is essentially attributable to its geographical origin and/or the human or natural factors there (p. 5).

GIs are a form of intellectual property, where a name is associated with a process or product's originating region or locality *as well as* a specific reputation for quality or authenticity. They can be applied to agri-food products, nonagricultural products, traditional cultures, processes, and production methods. GIs evolved from the French concept of *terroir* where a specific geographic locale whose natural environment, possibly in interaction with the climate or other natural phenomena, in combination with a traditional production knowledge, lead to a product that exhibits unique traits and reputation which are associated with the physical attributes of the natural environment or location-specific human capital where it was produced (Kerr and Yeung 2012). As with any knowledge, it can be used by others without attribution, meaning that the originator receives no return on efforts to produce that knowledge.

This lack of attribution or return on efforts to create knowledge has long been a public policy issue as the absence of reward creates an economic disincentive to create and innovate. It has also become an ethical issue when the value of traditional knowledge is not recognized and is freely exploited by others for economic gain (Isaac and Kerr 2003). In the case of geographic indications, it is the traditional ability to exploit unique physical characteristics to produce geographically unique products or to use location-specific (often traditional) knowledge in production that is open to free exploitation by others. Endowing those having that knowledge with intellectual property rights and commensurate legal protection is an attempt to correct an ethically based market failure.

GIs impart the exclusive right to market designated products from a particular geographic locale to a group of producers and processors. As consumers become more familiar with a particular GI, the value of that GI may increase, in a process comparable to that of developing a marketable brand name. The GI becomes a symbol for the relationship between the product's name, its special qualities, and its place of origin. It is important to note that a GI will protect a name and its *relationship* to a specific product, not the product itself. The actual product, its ingredients or formulation, independent of origin, is not protected by the GI. For example, a winemaker based anywhere in the EU can create a fortified red wine; so long as they do not call it "Port," it is a legitimate product. Only producers in the Oporto region of Portugal can call such a product "Port."

GIs signal a product's credence attributes to consumers. Credence attributes are characteristics of goods that cannot be detected by consumers, even subsequent to purchase and consumption, without some form of labeling. In the agri-food industry, credence attributes may include production methods (traditional, organic, free range), qualities (smoked, effervescent), source (local, Bob's family farm), or food safety characteristics. For example, even post purchase and consumption, an average consumer may not be able to organoleptically differentiate between olive oil that is grown in a famous, historic olive-growing

region of Greece, on trees grafted from the original Phoenician groves, and regular, conventional olive oil. The only means to indicate these unique traits is labeling (i.e., through a GI) and to take advantage of the marketing opportunity such labeling facilitates.

GIs are registered and protected in different forms across different countries and may be protected in one country but not another. In fact, many GIs have considerable profiles with consumers but do not enjoy universal GI protection because they are considered generic terms (i.e., their names are now in regular use as part of the common lexicon) in some markets. For example, Feta enjoys protected status as an inherently Greek product in the European Union (EU) but not in North America where the word "feta" can be used generically to describe a type of cheese, whether produced in Greece or not. Generic terms are a point of international contention because of this inconsistency in protection. Should the original producers of a GI product, name, or process neglect to register and actively protect that particular GI outside their domestic market, they risk losing their exclusive rights to it in those markets. This issue will be discussed in greater detail in a subsequent section.

Use and Status of GIs

GIs are increasingly popular amongst a broad range of stakeholders for a variety of reasons. Consumers benefit from GIs due to their provision of information, thereby reducing information costs and increasing transparency in the market (Josling 2006). Consumers may also benefit from a guarantee of quality provided by GIs. A growing segment of consumers are interested in a product's guarantee of origin whether for the particular place, production method, expected quality, or tradition. Reports indicate that consumers prefer and/or would be willing to pay a premium for the guarantee of origin and/or quality provided by a GI (Giovannucci et al. 2009). GIs enable producers to escape the commodity trap by conveying information about, and thereby, differentiating their product from those of competitors. This type

of differentiation provides a strategic form of competitive advantage that is not easily eroded while also providing a means of protection for the group's cultural or intellectual property (Giovannucci et al. 2009). Producers also benefit from the "feel good" factor of having their product gain recognition as being special (Kerr 2006).

It is also argued that GIs benefit their larger environment (rural areas, regions, and even countries) through improving the reputation of a place or region, with the potential for encouraging tourism, as well as providing the structure and means to affirm and place value on an area's unique sociocultural and agroecological traits, including quantifying the importance of "local" in products, production, and values. Producers', processors', and suppliers' incomes increase due to their associative relationship with the GI; economic development occurs based on the competitive advantage developed through utilizing local natural resources. Local or regional development initiatives are increasingly including GIs as a component due to this fostering of competitive advantage in natural resources. The EU has made GIs an essential element of its agricultural and rural development strategies (Josling 2006), significantly increasing the number, profile, and protection of recognized GIs. The EU is the most active proponent of GIs, with a total of 6021 protected GIs in 2009 (of which 5200 are wines/spirits and 821 for foods) and more are in process; the vast majority of protected GIs, many of them wines and spirits, originate in the OECD countries. While developing countries have innumerable products that are potential GIs, not many enjoy formal protected status as GIs; few currently have significant economic value beyond their domestic markets, and formal GI status would not necessarily increase their profile or demand in export markets.

The actual number and value of GIs is difficult to calculate, particularly in developing markets, or even on a global basis, due to different registration systems and the lack of a central registry. GIs that are protected as trademarks are difficult to differentiate from those that are not GIs, while difficulties also arise where GI registration systems overlap or are duplicated. The great variance in

protection systems used by different countries and their associated costs and benefits mean that a producer group must cautiously and completely assess a broad range of factors in deciding whether or not to pursue a GI registration as part of their export strategy.

How Are GIs Protected?

GIs require protection because, like any other brand, their names and therefore their intrinsic values are in the product's reputation or guarantee of quality. Fraudulent use of that name by imitations lacking the expected quality or reputation will erode its value. Protecting a GI is achieved through the granting of intellectual property rights (IPR), albeit this is implemented in practice in a number of different ways. Without adequate protection and enforcement of that protection, GIs invariably lose their geographic connection in the minds of consumers, allowing extra-regional competitors the opportunity to imitate the GI, free riding on its reputation. Eventually lack of protection and enforcement will result in a GI becoming generic where its geographic connection is universally and irrevocably lost as the name becomes part of common lexicon. Mocha coffee (originally of Yemeni origins) and Gouda and Swiss cheeses are examples (Giovannucci et al. 2009).

A protectable GI must have a geographic link that imparts a specific quality or reputation; therefore, most indications of source such as "Made in China" do not constitute a GI. A GI becomes protected initially in its country of origin through a variety of methods including, either individually or in combination, certification marks, denominations of origin, collective membership marks, trademarks, formal *sui generis* systems, administrative rulings, registers, and even under laws pertaining to consumer protection, unfair competition, and labeling (Giovannucci et al. 2009). This diversity of methods and systems contributes to the difficulties in accurately accounting for GIs globally as well as the potential for confusion and conflict. The combinations of legislation, regulation, and administration with the variance in

terminology used in intellectual property law further confuse a complex topic, even amongst legal professionals.

International trade agreements offer little enforceable protection for GIs. The Lisbon Agreement and Madrid Protocol both have diminished effectiveness due to limited membership and the inability to settle disputes (Kerr 2006). The Agreement on Trade-Related Aspects of Intellectual Property (TRIPS) of the World Trade Organization (WTO) provides the basic regulatory framework to protect GIs, but individual countries choose the method of implementation and degree of enforcement. Countries pursuing bilateral and regional trade agreements are increasingly including GI protection as components of such agreements. There is a push amongst some WTO member states to create a multilateral register of GIs that would extend greater TRIPS protection to GIs across foreign jurisdictions, with little consensus to date.

Some countries (e.g., the USA, Canada) use trademarks as part of their existing intellectual property protection regimes to incorporate GI protection. Other countries utilize a *sui generis* system to protect GIs. The EU has created a sophisticated and comprehensive body of GI legislation and regulations which focuses on the registration of protected designation of origin (PDO) and protected geographic indication (PGI). A PDO uses the name of a place whereby a product must be produced *and* processed within the defined geographic area, exhibiting qualities that can be attributed to that area, including natural and human factors (Giovannucci et al. 2009). A PGI is a more flexible designation as the product must be produced *and/or* processed in the defined geographic area. A PGI must exhibit some contribution from the defining qualities or characteristics of that area in its production and/or processing and/or preparation, but not necessarily the human contributions.

Collective marks and certification marks are other popular means of protecting GIs. Collective marks can only be used by members of a collective group, association, or cooperative to identify the connection between the goods/services they provide and their standards.

A certification mark is one that indicates the product or service has met standards and specifications, in production methods, for example, set by the owner of the mark. The owner of the mark controls its use but may not discriminate against any applicant who meets the set standards so long as the mark is used for the purposes for which it was registered.

Although both the USA and EU appreciate the value and function of GIs, they approach their protection of them in vastly different ways, both philosophically and methodologically. As some products and place names are protected in one market (EU) but are considered generic and therefore not protected in another (USA), IPR tensions can arise. Feta, port, cheddar cheese, mocha coffee, Worcestershire sauce, and Gouda and Swiss cheese are all examples of products whose original origins were geographic that do not have global protection (Giovannucci et al. 2009).

Attempts by the originating owners to reclaim a generic name in a process known as “clawback” invariably cause conflict as existing users of the generic name have vested interests in maintaining their use of the name. A Wisconsin cheese manufacturer that currently produces feta legally will be unwilling to relinquish the use of the word “feta” in describing its product. Should the EU be successful in its attempts to clawback the word “feta,” where only Greek holders of the GI “feta” could use that word to describe their cheese, the Wisconsin cheese maker’s ability to use “feta” to describe its product would be negated, necessitating finding an alternate name. If clawbacks are applied in developing country markets, as the EU is pursuing in its regional trade agreements, developing countries must spend their limited resources protecting the monopoly rents of foreigners (Yeung and Kerr 2011). In exchange for clawbacks, the EU is offering reciprocity by protecting developing country GIs in its market. As few developing country GIs have a profile in the EU, thereby negating the opportunity for rent seeking via clawbacks, reciprocity for developing country GI holders entails pursuing a greenfield GI development strategy, an endeavor that requires careful assessment.

Strategy for a Successful GI

While the success and benefits of GIs have been reported as general market trends in many studies as examined in Giovannucci et al. (2009), there is little empirical evidence showing that increases in producers' incomes can be singularly attributed to GIs. Most studies report price premiums which are attributed to GIs but fail to examine other market factors that may be contributing to the premiums achieved or the additional costs incurred to produce, establish, and maintain a GI (Kerr 2006). Many studies report potential benefits for producers including positive externalities such as preservation of traditional culture, community self-esteem, or improved organizational skills, all of which are beneficial in their own right, but such externalities do not constitute clear, empirical proof that GIs increase producers' incomes (Yeung and Kerr 2011). This paucity of empirical evidence raises a number of questions regarding the expenditures needed to support GIs as firstly, an agricultural and rural development tool, particularly for developing countries; secondly, a viable strategy for producers, again in particular for those in developing countries; and thirdly, as an instrument requiring further protection under commercial and international trade law. GIs present challenges in two main areas.

Establishing and maintaining greenfield GI development in new markets is a complex process. However it is registered and protected, either via trademarks or *sui generis* in its domestic market, significant additional transactions costs will be incurred in registering and protecting a new GI product internationally, given the fact that two main systems are in use globally. Prior to incurring the associated costs of seeking protection in foreign markets, however, a new GI must have a strong establishment strategy to support its success.

Markets for GI products are generally in developed countries where consumers have sufficient incomes to purchase products at premium prices. Yet such markets are characterized by fickle consumers for whom novel products are the norm. Garnering and sustaining their interest to generate more than passing initial success is a risky

endeavor. In order to achieve long-term success, a greenfield GI must have a strategic plan and a long-term commitment of resources to establish, develop, and protect it, both on the demand and supply sides of its marketing chain.

The value of owning a GI is its exclusivity (the monopoly on its use); strategically it must be recognized and then defended in an export destination's market. Gaining recognition in foreign markets will require the GI owner to demonstrate the inherent link and unique value between the product's quality and its GI to the appropriate foreign authorities in the registration process. The granting authorities may require that the owner of the GI demonstrate consumers' willingness to pay a premium for these quality gains. Such consumer research can be costly to obtain. If the GI is such a novel one that consumers have no experience with it, a consumer education and marketing campaign will be necessary prior to determining whether a price premium for such a product is warranted. Such a campaign has the risk of alerting potential competitors prior to the GI becoming protected in the destination market and creates a potential challenger in the registration process. Registration may be denied if domestic interests can illustrate valid objections. Thus, the registration of a GI in a foreign market must be strategic in its finances, timing, and execution as well as have strong counterarguments prepared for any potential objections.

Once the GI gains official recognition in the destination market, it must then be defended and its exclusivity enforced. The GI owner must monitor the market continuously for counterfeit products and/or infringement of the GI. Should this occur, the onus will be on the owner to inform the appropriate authorities in the foreign market and, subsequently, gather and present evidence of the transgression, including the potential preparation and financing of legal cases. The greater the success of the GI, the greater the potential for infringement and counterfeiting as competitors attempt to free ride upon that success. The nature of agri-food products has inherent safety risks, despite the most stringent production, processing, and distribution controls. A GI must have a disaster management plan to ensure safety and address any potential food

safety issues. Procedures for product recall, cooperation, and communication with local authorities and consumers and an emergency management plan must be prepared and ready to implement. Therefore, a GI's strategic plan must have a well-financed long-term commitment to monitor and protect it, including contingencies for avenues of legal action if necessary and an effective, rapid-response emergency disaster plan.

Once a GI is officially registered in the destination market, a comprehensive marketing effort must be launched to create the perception of value in the minds of consumers. Consumers in the destination market will need to be educated about the GIs existence and convinced of its special qualities that would make it worthy of a price premium as well as be provided with information regarding its preparation, storage, and use. Once the initial consumption experience proves positive, consumers must be moved from novelty to sustained consumption where dietary habits change to regularly include the GI or commit to the GI-based brand. This is a formidable challenge as the marketing efforts and resources devoted to GIs such as Kona coffee, champagne, or Columbian coffee can illustrate. If consumers cannot be convinced to regularly consume the GI beyond that first novelty "test-drive," the owners' investments to increase production for sustained export purposes may not be justified.

GIs also face supply side risks where long transport distances from field to foreign consumer, passing through many steps that can affect its quality, necessitate strong supply chain management. As vertical supply chain integration is often infeasible for developing country GI owners, independent contractors will handle the GI on its way to the final consumer. Whether such contractors are able or willing to maintain the GI's quality cannot be fully guaranteed. Quality in contents or packaging, timely and appropriate transport, perishability, optimal storage, timely shipping, and delivery are all aspects of a supply chain that can negatively affect a GIs quality and reputation, beyond the control of the producer. Effective supply chains manage information flows both up and down the chain (Hobbs 2001); managing information requires resources. The relationships

within the supply chain must also be organized such that GI holders capture a significant portion of the returns from the GI; producers in the developing world who undertake the effort to create and protect the GI should not bother if they cannot capture a considerable amount of the extra value created by the GI (Yeung and Kerr 2011).

Within the producer group that owns the GI, stringent quality controls must be created and enforced to ensure the quality of the product. The group must collectively support and internally enforce the GIs standards while managing group dynamics and settling internal disputes, all in the name of preserving the GI's quality. The GI's producers each have a stake in each other's performance and the product's integrity and success, as well as an equity share of the value of the GI. They must also be able to manage any changes, hopefully due to success, that the GI garners, whether a need to expand production, respond to consumer demands, manage new producers who want to produce the GI, production of new products under the GIs reputation, undertake alternative marketing initiatives, address issues of tradition compared to innovation, etc. The producer group that owns the GI must be able to anticipate change and have the means to adapt. They must also have a long-term and dynamic business plan that will provide a mechanism for effective supply chain management and address any threats to their exclusive monopoly that may arise due to their success.

Each of these elements contribute essential components towards a GI's commercial success in a foreign market. As Josling (2006) notes regarding the success of some EU GIs:

A quick glance at the scale of production of many of the GIs suggests they are not geared toward global markets. Many names protected by GIs would not be recognised in other parts of the same country, let alone in other member states in the EU. So the role of these GIs in marketing is unclear. If small groups of producers choose to register their name and production process, . . . they are unlikely to benefit from sales beyond their own region if the information is not meaningful to more distant consumers (p. 360).

This strategy also demonstrates that GIs are not a rapid solution to low returns for agricultural

producers, despite some benefits for developing countries incorporating GIs in their export-oriented development strategies. A GI's success depends on the ability of producers to capture any competitive advantages endowed through human and natural resources as well as their ability to convey meaningful information to consumers. This requires a certain level of organizational skill and resources to maximize any rents garnered by a GI designation, which often does not exist in developing countries. For developing country producers, greenfield GI development in developed markets is a risky and expensive strategy; given that evidence of the ability of GIs to increase producers' incomes is weak, recommending that developing countries expand the role of GIs in their development policies is complicated. Consequently, furthering the protection of GIs at the WTO on the basis of reciprocal protection in developed countries' markets may not represent the best option for developing countries (Yeung and Kerr 2011). While developing countries should access GI protection in developed countries where the situation warrants, whether via trademarks or *sui generis*, encouraging developing countries to actively pursue development strategies based on GIs should be deferred until the efficacy of GIs in generating sustained increases in producers' incomes can be credibly assessed.

Summary

Geographic indications are a form of intellectual property protection that protects a link between a product's (or process's) place of origin and specific qualities or reputation attributed to that place of origin. GIs provide information to consumers about a product's credence attributes and are used by a collective group of producers as a type of guarantee that the product (or process) is authentic.

GIs are protected through a variety of methods, including as trademarks within the existing IPR systems of countries *sui generis* systems, and collective and certification markets. This broad range of methodologies makes it difficult to accurately

measure the actual number of GIs in use around the world, or even in specific countries; it also creates tensions between countries that use different systems to protect GIs. GIs can be protected in their domestic market but not in foreign markets due to these differences in systems. The use of a GI's name can become generic where the inherent connection with its place of origin is irrevocably lost in the mind of consumers. Attempts to regain the exclusivity of a generic GI by the originating country are known as clawback. Clawback is controversial as foreign firms legally using the generic name have vested interests in maintaining that use.

Seeking a GI designation in foreign markets as an export strategy is a complex and costly process, particularly for developing country producers. They must have a long-term commitment of finances and resources to ensure the successful registration, marketing, and protection of the GI in that specific export market. They will face demand side challenges and challenges along their supply chain as well as change management issues. For any long-term commercial success, they must have a comprehensive strategic plan for that GI in that particular market as well as some essential organizational skills and resources, which often simply do not exist in developing countries. GIs are therefore a highly risky and expensive undertaking for producers from developing countries.

GIs originating in developed countries have proven to be popular tools for their producer groups with many positive externalities and the potential to expand exports. The differences between the circumstances of developed and developing country GIs, however, greatly influence their potential export success. Developed country GIs tend to already enjoy consumer awareness and use in their destination markets prior to becoming GIs, thereby reducing their establishment costs in foreign markets. Developed country GIs enjoy the IPR protection benefits of well-established government institutions, infrastructure, programs, and systems. Their producers have easy access to information, assistance, services, and support for their GI, all of which may not be accessible or available to producers in developing countries.

That is not to say that developing country producers should not export their GIs or seek GI protection in foreign markets should their individual circumstances allow, but, positive externalities aside, until there is credible empirical evidence proving the efficacy of GIs in increasing producers' incomes, producer groups must carefully weigh the full costs and benefits of such a strategy. Similarly, developing country governments should reassess any development strategy that relies on exporting GIs to developed country markets.

Given the paucity of evidence illustrating that rises in producers' incomes can be singularly attributed to GIs, particularly in conjunction with the costs incurred in pursuing, establishing, and protecting the GI, recommending that developing country producer groups pursue a greenfield GI export strategy in developed country markets would seem a risky use of their limited resources.

Introduction

Over the past two decades, geographical indications (henceforth GIs) have been at the center of a tensed international debate. Favoring their enforcement, some argue that GIs comprise the best legal tool for defending regional culinary cultures, including those of emerging countries, whose producers have little means for independently claiming reward for their most original work; thus, as noted in a United Nations Conference on Trade and Development (UNCTAD) study, GIs “reward producers that maintain a

traditional high standard of quality, while at the same time allowing flexibility for innovation and improvement in the context of that tradition” (Downes and Laird 1999, p. 6). On the other hand, major international corporations – voicing their position especially within the WTO (Handler 2006) – have stressed that GIs create monopolistic opportunities, obstaculating free trade around the globe. Further criticisms, finally, point out that GIs are inefficacious in rewarding the people from within the know-how originated. After a summary of the historical and legal highlights regarding GIs, the entry addresses the main meta-physical and ethical interrogatives surrounding GIs of agricultural origin, in connection with the identity of the food product and its cultural underpinnings.

Historical and Legal Highlights of GIs

GIs are one of the oldest and most renowned ranks of entities covered by intellectual property right in modern history (see O’Connor 2004). Their role is to protect the essential contribution of a geographical location in the making of a product, provided by special climatic, geological, and biotic conditions and by a *sui generis* know-how. GIs protect goods of all sorts, including jewelry, textiles, and handicrafts. The vast majority of GIs, however, are agricultural products, in particular wines and spirits. Some early and well-known specimens include Chianti Classico wines, whose geographical area of production has been specifically designated since 1716; Tokaj-Hegyalja wines, whose threefold classification was introduced in 1730; Champagne wines, invented at least in 1531, defined in 1662, and then protected from 1891; and Port wines, specially denominated and regulated since 1756.

Four major agreements over the last 130 years have come to define the legal status of GIs: the Paris Convention for the Protection of Industrial Property (1883); the Madrid Agreement (1891); the Lisbon Agreement for the Protection of Appellations of Origin and their International Registration (1958); and the Agreement on Trade-Related Aspects of Intellectual Property

Rights (1994), henceforth abbreviated as TRIPs. Articles 22 and 23 of the TRIPs, signed within the WTO by 117 countries, regulate to these days the protection of GIs at the international level. Article 22.1 establishes that

Geographical indications are, for the purposes of this Agreement, indications which identify a good as originating in the territory of a Member, or a region or locality in that territory, where a given quality, reputation or other characteristic of the good is essentially attributable to its geographical origin.

The comma sets GIs as a more restrictive legal category than “indications of sources.” An indication of source, indeed, may more modestly flag that a good was once invented, tended, and fabricated in a certain region. This does not imply that the good, whose source is indicated, was produced in the region where it first originated. Indications of source, that is, establish a generic tie between a kind of good and a geographical area. On the contrary, a GI implies a specific tie of the labeled product to a geographical region: for instance, each single bottle of Port wine must come from the Port district in Portugal.

Article 23 of the TRIPs, then, bestows an even higher level of international legal protection to wines and spirits. In fact, the Article requires that each member country “to prevent the use of such GIs irrespective of whether the consumers are misled or whether the use of such indications constitutes an act of unfair competition” (Das 2006, p. 463). Wines and spirits, protected by an “appellation of origin” as specified in Article 23, enjoy labels that have a more restrictive legal status than generic GIs in two respects. First, appellations of origin must indicate a geographical area, whereas some GIs may be attached to a non-geographical descriptor, such as Basmati (which refers to a variety of rice, rather than to a region of production). Secondly, the more generic reputation of a product is not sufficient to establish an appellation of origin; the essential tie to the geographical area must be proved (cfr. Das 2006, pp. 462–463).

Five aspects of the ways GIs are understood under the TRIPs are particularly relevant from a philosophical perspective:

- (i) GIs are treated as intellectual property rights.
- (ii) GIs are identified through relationships with a spatial region.
- (iii) GIs are identified with respect to no temporal limit.
- (iv) GIs are identified through some *essential* properties of the protected items.
- (v) Recognition and protection of GIs is left to each individual country.

In other words, for any item that is ranked as an instance of a GI, some individual or corporation may claim its exclusive ownership (i). The ownership in question stems from the relationship between the item produced and a certain portion of land (ii), which is not temporally characterized (iii). Not all the items produced on that land, however, qualify to be protected under the GI; a GI is a method of ranking items based on whether they present those traits that essentially define the intellectual novelty to be protected under the agreement (iv).

Chianti Classico is a case in point of GI. A wine can be included under this rank only if the grapes from which it originated were grown in specific portions of nine townships in Central Tuscany, between the provinces of Florence and Siena. The property right over items produced in these territories does not have any temporal limitation; in order to qualify as Chianti Classico, a product must fulfill a relatively long list of requirements, including grape variety, fermentation techniques, organoleptic aspects, and bottling restrictions.

A widespread belief among consumers has it that – as Sophie Reviron et al. recently put it – “GIs are not only a business but part of a regional patrimonial strategy, perceived to be for the benefit of both farmers/processors and consumers” (Reviron et al. 2009, p. 27). Is this really the case? On which grounds can the introduction of a GI such as Chianti Classico be, metaphysically speaking, accounted for? In other words, which features of the wine can serve to justify a claim of intellectual property right and the introduction of a rank with the five above specified characteristics? Two principal methodologies for answering this question have been advanced, one centered on

the concept of *terroir* and the second resting on scientific considerations. Both are liable of important criticisms.

The View from Terroir

The most common argument in defense of GIs is that they stem from and are key to protect specific *terroirs*. “Over recent years, place has come to play a central role in defining the character and quality of agricultural products” (Demossier 2011, p. 685); the trend goes hand in hand with the rising importance of *terroir*, a concept that has no easy metaphysical analogues. A great deal of publications in the social sciences has been devoted in the past dozen years or so to uncover the nuances of such a concept. *Terroir* is supposed to capture some qualitative aspects of an item while being unable to pin them down specifically. Thus, the *terroir* of the wine in a Chianti Classico bottle is a qualitative aspect of the wine itself, derived from the biotic conditions of production (the rocks, soil, air, plants, insects, birds, yeasts) as well as the complex system of practices – often indicated under the expression “know-how” – that yielded it.

Accounts of GIs based on the specificity of *terroir* seem to be disputable for two main reasons. First, because the economic model promoted by GIs seems to defy the condition of localized know-how embedded in the definition of *terroir*. Indeed, once a GI is bestowed upon a certain product, its increased economic attractiveness encourages heterochthone investors and workforce to take part in the production process. Recent trends in wine production, for instance, bear witness to this. Just to stick to the example cited above, a large proportion of Chianti Classico wines are owned by investors that would not identify themselves as inhabitants of the region; at the same time, a large percentage of the workforce comprises recent migrants from Macedonia, Albania, and countries in Northern Africa (cfr. Cicerchia 2009). While such a trend may increase creativity in wine production, it flies in the face of those arguments relying on the stability of wines’ know-how.

Secondly, GIs have no temporal boundaries, yet climatic, geological, and biotic conditions within *terroirs* change, sometimes drastically, over decades and centuries (cfr. Ingold 2000, chapter 11). For instance, the environmental conditions in the Champagne region have considerably changed over the past five centuries, thus making unclear what are the essential characteristics that the GI over Champagne wines aims at protecting.

The concept of a GI is often equated to the one of *terroir* in the relevant literature; a sample is the following passage by Tim Josling: “The form of intellectual protection known by the term ‘geographical indications’, or GIs for short, is central to providing the concept of *terroir* legal expression” (2006, p. 338). However, as the remarks above underline, there are some important distinctions between “*terroir*” and “geographical indication.” The latter is a legal category defined through an essential tie to a geographical location, with important economic implications, as Addor and Grazioli underline:

In consequence, the improved protection of geographical indications for all products on a level similar to the one granted at present for wines and spirits, would promise trade and investment advantages, in particular for all these developing and developed countries which depend on exports of primary commodities. Extension is thus an economical asset for countries wishing to maximize the benefits from the excellent reputation of many of their products in order to consolidate their markets and avoid illegitimate use by and identification of products manufactured outside their borders. (Addor and Grazioli 2002, p. 896)

The economic advantages offered by GIs, however, have tended with time to alienate local producers from their product and may prevent the due flexibility in order to keep track of changing conditions in the environment of production and in the relevant know-how. *Terroir*, on the contrary, is a cultural concept, with scarce legal efficacy, enjoying far more flexibility with respect to the changing of specific environmental conditions and of the traditions of human tender.

The View from Science

Another approach to GIs seeks out to uncover their peculiar biochemical characteristics. Modern chemistry successfully identified chemical compounds such as water in terms of necessary and sufficient conditions based on a typical structure; can similar conditions be offered also for cheeses, teas, wines, spirits, and the like? A trend of research moving in this direction gained increasing credibility over the last 15 years (see Baxter et al. 1997, represents a pionieristic study in the field, moving from the analysis of Spanish and English wines). The idea is to pair a specific agricultural product to certain values of (bio) chemical compounds that are specific to that product, under the conviction that such values reflect the specific environmental conditions within which the product originated. For instance, Angus et al. (2006) have shown that wines made from grapes grown in different regions of New Zealand will be distinguishable, with a degree of accuracy of 80% circa, based on the amounts of nine of chemical elements (Sr, Rb, Ni, Co, Pb, Mn, Cd, Ga, and Cs) that they contain.

Notwithstanding the difficulty of the enterprise, let it be granted that one day appropriate techniques will be in place to fully read the unique chemical structure of each sample of an agricultural product; how could such data be put to use in order to delimit the boundary parameters of a GI is still unclear. The complexity of the issue is not merely practical: the point is conceptual. An agricultural product is not just a chemical formula but an artifact, identified also via nonscientific aspects such as farming methods (e.g., organic) or the tools used to produce and package it. In other words, the identity of a GI, thus far, does not depend solely on its *natural* aspects but also on the *process* through which it is produced. As a forged painting and the original may not differ at all materially, while still being quite different artworks, so a GI cannot be equated to its material constitution: some aspects of its making are key to its identity. The upshot is that the chemical or biological data, which allegedly help fixing the identity of a GI, need be

accompanied by some requirements as to the process of production.

G and I the Protection of Culinary *Milieus*

Despite the difficulties in ascertaining sufficient grounds to comprehend their conditions of identity, GIs arguably constitute an efficacious legal tool to prevent the exploitation of cultural *milieus* both within the country of origin of the product and at the international level. It is for this reason that, in recent years, some authors (on behalf also of GI producers) have argued for a strengthening of the international legal tools available to prevent infringements (cfr. Vittori 2010), such as an extension of the rights granted under Article 23 of the TRIPs – now limited to wines and spirits – to all GIs (cfr. Addor and Grazioli 2002; Das 2006). The rights would allow producers of specialty foods (as well as nonagricultural products) to see recognized the novelty of their produce, without the risk of unfair imitation. No doubt, such a scenario would open up new economic opportunities for many small producers in less affluent countries. In an optic of preservation and valorization of local traditions as well as promotion of small economic entrepreneurs, this seems a legal scenario with beneficial implications also from an ethical perspective.

On the other hand, according to some, GIs are trade-distorting legal tools; in the words of Josling,

To some countries, GIs are an unnecessary and undesirable form of protection for producers in a particular region against competition from new entrants. If a type of product traditionally associated with a geographical region can be successfully produced in regions other than that which gave it its name, then any restriction on the competitive new product is likely to be resisted. If the new producer is located overseas then the restriction is presumably trade-distorting. (2006, p. 340)

There is indeed the possibility that some producers, working in a geographical area outside the one essentially associated with a GI, place on the market items comparable in terms of characteristics and quality to those items that are bestowed

the GI label. When this is the case, the legal restriction imposed by the GI appears to be a simple branding measure, an obstacle to free trade. At the same time, it must be recognized that, in several occasions, new entrants operate in bad faith: they exploit the reputation on the market of a certain product by creating an imitation of lower quality.

GIs seem, then, the best measure so far devised to cope with those operating in bad faith. The question is whether they are an effective tool. Besides the practical difficulties of legally enforcing the rights associated with a GI at the national and international level, two additional drawbacks of GIs may be pointed out, one concerning the “boomerang effect” of GIs and the other regarding GIs and food authenticity. To begin with the former, in an initial moment, GIs empower producers of a local specialty with an exclusive right to a certain etiquette. As described above, however, in a successive phase, the attractive opportunity of a market exclusive product recalls also the attention of heterochthone investors and work labor, which may end up alienating the very initial producers from the good they initially wished to see protected. Thus, while Chianti Classico producers and workforce may have been initially locally sourced, the situation is now reversed, so much so that the original population involved in the production of this GI is now largely alienated both as a producer and as a consumer. This may be described as a “boomerang effect”: a GI creates a brand representing a specific relationship between a people and a land, through which conquering new markets; renewed attention on the GI recalls heterochthone investors and workers, which end up transforming the production process in order to suit the new markets.

Secondly, GIs do not necessarily align with basic claims of product authenticity (see ► “Authenticity in Food”). For instance, while the environmental conditions and the practices of human tender of wineries in the Port region may drastically change to the point of suggesting to autochthones that the authenticity of the product was compromised, the GI would continue to support labeling the wines produced as authentic Port

wines. Arguably, analogous circumstances have obtained with respect to a number of GIs, thus revealing the shortcomings of GIs as a legal measure protecting local food cultures. If, on the other hand, claims to a GI are justified in terms of the unique chemical composition of the produce, the authenticity of the process of production is left out of the identity of the product, thus removing from the picture the significance of human tender.

Summary

Geographical indications are among the earliest sorts of entities covered by intellectual property right in modern history, having been in usage since 1700s. Their legal enforcement today is regulated under Articles 22 and 23 of the Agreement on the Trade-Related Aspects of Intellectual Property Rights (TRIPs Agreement). From a metaphysical point of view, the identity of GIs may be accounted for under two alternative perspectives, one resting on the concept of *terroir* and the other based instead on distinctive biochemical characteristics of a product. Both accounts result problematic. Finally, the entry assesses the efficacy of GIs in protecting food *milieus*: while GIs are the best available legal tool to protect food *milieus*, they come short in preventing the alienation of local producers from their products as well as in ensuring the authenticity of a product.

Gluttony

Trevor Smith
Department of Philosophy, Marquette University,
Milwaukee, WI, USA

Synonyms

Drunkenness; Edacity; Gormandizing; Intemperance; Overeating; Overindulgence

Introduction

Gluttony describes either (a) the action of over-indulging in food or drink or (b) a state of

character in which one regularly overindulges in food and/or drink. Gluttony is recognized by most moral and ethical codes, except for the most ardently hedonistic, as a moral failing. While the term “gluttony” has etymological roots in Latin and Old French, the moral assessment of gluttony, in the Western world, goes as far back as the Ancient Greeks. Presented here is a brief historical sketch of the concept of gluttony as understood in the Western world. Changing conceptions of gluttony will be traced from Ancient Greek philosophers through the Judeo-Christian understanding of gluttony as a sin and to the way that gluttony has become intimately connected to moral judgments of fatness.

Ancient Greek Views on Gluttony

Plato (427–347 BCE) and Aristotle (384–322 BCE) are undeniably the most important and influential moral thinkers of the Ancient Western world. Both, as virtue ethicists, present normative theories of ethics in which gluttony, as overindulgence in food and drink, plays a unique role. The philosophical views of Plato and Aristotle are intimately tied, as Plato was Aristotle’s teacher, yet their views on ethics (and therein their views of gluttony) are quite different. The relationship between Plato and Aristotle is possibly best captured by Raphael in his fresco “The School of Athens” (“Scuola di Atene”) which was painted in the Apostolic Palace of the Vatican in the early sixteenth century. Here, surrounded by philosophers, mathematicians, and thinkers of the Ancient world, Plato and Aristotle stand side-by-side, at center stage, under a vaulted arch. Plato, holding a copy of the *Timaeus*, is pointing towards the heavens and the abstract world of the nonmaterial. Aristotle, holding a copy of the *Nicomachean Ethics*, is gesturing downwards, towards the material and scientifically understood world. While both Plato and Aristotle hold similar philosophical ideas, they advance these theories in reference to radically different ends leaving their accounts of virtue, the human life, and gluttony related yet radically different.

Plato on Gluttony

Plato’s understanding of gluttony, as a form of moral failing, can be found scattered throughout his writings, but his most influential argument is presented in the *Republic*. Plato’s general understanding of the human life and its purpose can be grasped by looking at the famous Allegory of the Cave (The Republic 1997, pp. 1132–1135). This allegory describes a group of prisoners held captive in an underground cave. The prisoners are tied down and forced to stare at shadows as they dance on the wall in front of them, spending the entirety of their lives seeing and understanding only these shadows. From among these prisoners, one is able to break free from their restraints, enabling them to turn around and see the fire which casts the shadows. Eventually this prisoner is able to climb out of the cave and into the sunlight where she can, for the first time, come to see the world in full vibrant color as illuminated by the sun. This allegory, for Plato, represents the life of the philosopher who, alone, can escape the trappings of the material world (comprised of false representations and epistemological missteps) and come to full knowledge of reality, life, and the good.

Plato’s vision of life’s purpose is intimately connected to his understanding of epistemology. For Plato, the material world is one of constant change and speculation. Knowledge is gained when the mind moves beyond the physical and material world to understand the immutable essences. For Plato, the highest function of humans is to be found in the mind, and the highest purpose of the mind is the acquisition of knowledge.

While Plato ultimately places all value and purpose in the pursuits of the human mind, he does account for the human body as it too has a purpose and must be understood ethically. For Plato, proper health, and therein the proper functioning of the mind, is essential for the philosophical goal of knowledge in that people are bound to their bodies and bodies act as vehicles of the soul. When the body suffers, or is put into an unhealthy state, the physical existence of a person will detract from their ability to achieve the highest

purpose of knowledge. Thus, bodies and bodily health are necessary instrumental values for the achievement of knowledge. Individuals are required to tend to their bodies as a way of ensuring that the pursuit of knowledge is uncorrupted and undeterred.

Plato's understanding of gluttony, or over-indulgence in food and drink, is explained through the virtue of temperance (Hill 2011). Temperance is the control of one's physical desires. The good life, or the life of knowledge, can only be pursued and achieved by controlling these desires and acting on them in the right way. Those who cannot control their passions towards food and drink are scorned by Plato, as these gluttonous individuals remain tied down and tethered, like prisoners, to their physical existence and are thus unable to properly pursue the higher faculties of reason. For Plato, when one allows their physical desires to control their life, their rational faculties become enslaved to their physical desires. These gluttonous individuals are denied the highest human pursuit of philosophical knowledge.

Broadly speaking, Plato's understanding of gluttony, as an overactive and overfed appetite, is presented as morally problematic because this overindulgence denies the flourishing of the higher faculties of the mind. Gluttony is the ultimate act of intemperance, the earmark of the ignorant and simple, and is to be avoided at all costs.

Aristotle on Gluttony

Aristotle's understanding of gluttony is somewhat similar to Plato's in that gluttony describes the actions of the intemperate person. Whereas Plato characterizes the highest good and the best life as a life of the mind in abstract contemplation, Aristotle conceives of the good life as the complete flourishing of the totality of human capabilities such that happiness (*eudaimonia*) can be achieved. While Plato advances an ascetic view that the life committed solely to contemplation is the good life, Aristotle believes that contemplation must coincide with pleasure for the achievement of happiness.

Aristotle's teleological conception of life is outlined in Book I of the *Nicomachean Ethics*, and most of the rest of the book is devoted to the task of outlining, defining, and explaining the virtues and the way virtue is acquired. Aristotle's most important contribution to the tradition of virtue ethics is his description of moral virtues as an intermediate, or "mean," state which lies between two extremes, one of excess and one of deficiency (Aristotle 1941, pp. 958–959).

Aristotle's condemnation of gluttony is explained as a failure of the virtue of temperance. Temperance is the virtue that governs the human capacity for pleasure regarding the physical body. While temperance governs the desires for sex and drinking, it also governs the desires for food. Temperance *qua* food, as the proper control of one's desires to eat, exists as a mean state intermediate between a vice of excess (where one desires food too much or in the wrong way) and a vice of deficiency (where one lacks a desire for food). Through critical self-reflection and reinforced positive actions, done under the guidance of practical reason, individuals can habituate themselves to develop a moderated desire for food where food is desired in the right way, at the right time, in the right amount, and for the right reasons. Aristotle notes (Aristotle 1941, p. 982) that there are few people who suffer from a lack of desire in regard to temperance *qua* food and drink, and thus the moral concerns regarding food-related desires are, by and large, worries about an over-willingness to indulge.

The failure to properly control one's desires for food and drink is a moral harm for Aristotle in that an overindulgent person's desires will prohibit her from habituating other virtues and achieving the complete life. In one respect, the overindulgent person will harm their health, and without health one cannot pursue all the goods of life and will thus fail to achieve true happiness. In another respect, the overindulgent person's uncontrolled desires for pleasure will lead them to states of ignorance. These states of indulgence and ignorance, while suited for grazing animals (Aristotle 1941, p. 938), do not describe the full flourishing of human life as humans possess faculties beyond physical appetites. Thus, in some ways, Aristotle

mirrors Plato's view of the instrumental good of the body and health and notes the ability of unchecked physical desires to distract from the rational goods of the individual. Yet while Plato privileges the life of the mind as the only pursuable good, Aristotle wants to conjoin this with an evaluation of pleasure as important and good in many respects. Plato seeks to transcend the body and views the material existence of humans as a regrettable yet necessary aspect of life, while Aristotle seeks to fulfill the body under the guidance of reason as both the rational and physical aspects of life contribute to one's happiness. For Aristotle, the pleasure that one draws from food is a good to be pursued, and physical pleasure is an important aspect of life when rationally guided, controlled, and moderated. Gluttony then is a form of unrestrained desire which harms the individual in their pursuit of the complete life.

Gluttony in Christianity

The most iconic understanding of gluttony in the Judeo-Christian world is tied to its inclusion as one of the so-called seven deadly sins. While capturing certain moral and ethical proclamations found in the Bible, the identification of gluttony as a moral transgression carries with it not only a theological message of moral failure but also a long history of artistic and literary depiction.

The seven deadly sins, of which gluttony is one, trace their origin to the Greek monk Evagrius Ponticus, who in the fourth century outlined gluttony as one of the "eight principle temptations" (also known at the "eight patterns of evil thought"). John Cassian, Evagrius Ponticus' student, translated this work into Latin and brought the "eight temptations" to Western Christendom. Two centuries later, in 590, Pope Gregory I revisited and revised these eight patterns, reducing them down to a list of seven and issuing them as "the seven deadly (or mortal/capital) sins."

Interest in the seven deadly sins was popularized in the fourteenth century when Dante Alighieri, in his *Divine Comedy*, immortalized the seven deadly sins by enshrining them as levels of hell. Gluttony is described by Dante in Canto

VI where, in the third level of hell, gluttons are tormented by Cerberus as they wallow and float like swollen logs in a putrid bog of filth. Following Dante, in the fourteenth, fifteenth, and sixteenth centuries, theologians assigned specific demons to the seven deadly sins, claiming that either Beelzebub or Belphegor (each was one of the so-called seven princes of hell) was the demon responsible for tempting people into the sin of gluttony. Late Medieval and Renaissance artists, such as Nardo di Cione, Taddeo di Bartolo, and Hieronymus Bosch, visually depicted sin (and its related demonology) in paintings, sculptures, and reliefs, often portraying the glutton as a ravenous and hedonistic individual plagued by horned demons and physically suffering at the hand of their desires.

This history of the Christian sin of gluttony, as intertwined with theological and artistic depictions of hell, perdition, and demons, has resulted in gluttony being identified with highly visual and visceral images of damnation and lecherous corruption. Interestingly, this visceral imagery of gluttony is not found in the Bible, although the scriptures do present gluttony as moral transgression.

At the root of the identification of gluttony as sinful and wicked is the way gluttony acts as a form of idolatry. Individuals who overindulge their appetites for food or drink value too highly the pleasures they receive from these indulgences. These pleasures become the object of striving and individuals who overindulge shift their focus from the divine to objects of consumption. The gluttonous person, whose eyes are looking towards their belly, is described as one who has their mind set on only earthly things (Philippians 3:19 New International Version). This shifting of focus, from the divine to the worldly, is way of replacing a striving towards God with a worship of all things physical, pleasurable, and material. For the gluttonous, the quest for holiness has been exchanged for the satisfaction of desires, whereas food and drink are worshiped and consumed in excessive amounts as if these consumable goods were of the highest purpose. In this way, gluttony becomes the practice of a life lived in devotion to pleasure and not God. Idolatry, and the worshiping of

anything above God, is a cardinal sin in that the conception of divinity in Christianity is singular and monotheistic. God, and God alone, is to be worshiped. The centrality of this claim is repeated throughout scripture and is, famously, the first of the Ten Commandments handed down by God to Moses (Exodus 20:3, Deuteronomy 5:7 New International Version). While idolatry is most often associated with worshiping so-called false gods, it also captures the possibility of worshiping objects as if they were God. Gluttony, as a way of turning away from God and towards pleasure, makes a false idol out of food and drink and thus pulls one into the false worship of a false god.

Three things should be apparent in Christianity's assessment of gluttony as a form of idolatry. First, the assessment of gluttony as a form of idolatry does not privilege gluttony as either the ultimate form of false worship or a variant of false worship which is uniquely pernicious. Similar claims of idolatry can be found in scripture about the worship of money and the associated sin of greed or avarice (Matthew 6:24 New International Version) and the worship of sex and the associated sin of lust (1 John 2:15–16, Matthew 5:28 New International Version). Gluttony is merely one of many ways one may overindulge in earthly pursuits such that one comes to worship objects rather than God. Second, it is noticeable that the root of the negative assessment of gluttony found in Christianity is not a condemnation of fatness. The sin of gluttony is not rooted in aesthetic judgments about beauty or body shape, and social stigmas and assumptions about physical standards of taste have no bearing on the prohibitions on gluttony. Gluttony is the shifting of devotion away from God, not a proclamation of a specific vision of beauty standards. Thirdly, the condemnation of gluttony in Christianity is not a judgment of the baseness of food and drink in-and-of-itself. In fact, food and drink plays an important role in Christianity. Most notably, food and eating is at the center of the sacrament of communion, the miracles performed by Jesus often involved food and drink (such as turning water into wine at the wedding in Cana, the feeding of the 5000 from fishes and loaves, the miracle of the draught of fish, and the catching of the

153 fish), and the consumption and sharing of food (both as a religious practice and an act of charity) is a common motif in biblical stories and parables. Scripturally, Christianity does not advance a conception of asceticism or the ascetic life. The moral concerns about food focus on the temptation to supplant the value and prestige of God with a value of pleasurable consumption and are thus not a condemnation of all things physical.

Gluttony's Nineteenth Century Connection to Fatness

Historical understandings of gluttony were, by and large, disconnected from an assessment of body types and body shapes. The immorality of gluttony before the mid-nineteenth century had little to do with fatness and was rather centered on either (a) describing the harmful effects of uncontrolled desires or (b) the ability of unrestrained behavior to distract one from the proper worship of the divine. This assessment has shifted. Since the mid-nineteenth century, gluttony has come to be associated with social, aesthetic, and medical judgments about fatness.

Up until the mid-1800s, fatness (in the Western World) was, for the most part, linked to wealth, health, and prosperity (Schwartz 1986). Fatness was a luxury of privilege and indicated a lifestyle above the toil of physical labor and beyond a meager existence of subsistence eating. While individuals, such as Daniel Lambert (a famous British man who weighed in excess of 700 lb), who were “excessively fat” were mainstays in spectacle shows (or so-called freak shows), fatness was, to a point, socially accepted as a status symbol. In the mid- to late-nineteenth century, this social image began to change in conjunction with growing critiques of opulence and wealth. As social and economic critics began to target privileged classes and question the justice of accumulated wealth, fatness transformed from an image of prosperity and high social status to one of corruption, excessive opulence, and oppression. Industrialists and capitalists, by the 1920s, were being described as “fat cats” and unjust opulence began to become associated with

bloated laziness and decadent lifestyles (Ayto 2006).

In conjunction with the social shift in the understanding of fatness came a change in the medical understanding of body shapes. Up until the mid-nineteenth century, medical professionals were not concerned with the health effects of fatness and rather focused the perils of those diseases that caused chronic wasting (Farrell 2011). As social attitudes towards fatness shifted, so too did medical attitudes. The mid-1800s saw a sharp rise in “medical” treatments for fatness, some from medical professionals and others from savvy entrepreneurs looking to capitalize on anti-fat biases. Dietary weight loss cures were marketed in magazines and traveling salesmen hawked miracle weight loss devices. By the early 1900s, fatness had become a medical concern, and medical opinions about body shape and size had become a central preoccupation (ibid).

The shifting of social and medical attitudes surrounding fatness has persisted to the present day. Fatness is still the subject of ridicule, particularly in regard to women, as well as a continued source of spectacle, as seen in the plethora of reality TV shows concerning weight loss challenges for the fat. Additionally, fatness has remained the focus of health campaigns as seen in First Lady Michelle Obama’s “Let’s Move” campaign which targets fatness and obesity in children. These continuing negative attitudes towards fatness have resulted in what some call “anti-fat bias.”

As anti-fat bias has persisted and grown, so too has the social view of gluttony. Individuals who are labeled as fat have become stigmatized as gluttonous and edacious. Research into social perceptions of fatness and gluttony has revealed that gluttonous overeating is perceived as the cause of obesity and fatness. Joint research from the University of Virginia, Yale University, and Oxford University revealed that test subjects displayed not only explicit and implicit anti-fat biases but connected these biases to ascribed gluttonous overeating done by “overweight” people (Teachman et al. 2003). Researchers found that while providing information demonstrating a medical cause of fatness and obesity (such as an

established thyroid condition) lessened the negative judgments of test subjects towards fat people, subjects (a) still negatively judged fat individuals even with medical or genetic conditions which predispose them towards larger body types and (b) still identified overeating as the cause of obesity both in these individuals as well as in society writ large.

What this study helps identify, along with other similar studies (see Chlouverakis 1975), is the assumption that gluttony is the cause of fatness. Gluttony has become a post hoc explanation for fatness, and the negative assessment of this fatness can be traced to the perception of gluttonous indulgence. For the tested subjects, despite being confronted with evidence to the contrary, gluttony is the only possible reason that someone could become fat. Since, for these people, being fat is bad, gluttony, as the cause of fatness, is also bad.

If this research data is true, what it indicates is that the persistence of fat biases influences, socially and culturally, the way individuals view gluttony both in cases where the gluttony is real and where one erroneously perceives it to be the cause of fatness. In this way, gluttony has become not only intimately tied to social norms about body shape but the way in which anti-fat bias is grounded and explained in negative moral assessments. In comparison to historical views of gluttony, this modern understanding of gluttony is now tied to social and cultural judgments of fatness.

Leaving the Language of Gluttony Behind

Recently there has been a trend, in both social and medical communities, to move away from the language of gluttony in favor of new language, and therein new understandings, of overeating. For some, the language of gluttony has become antiquated and undesirable. The reason for this change is that gluttony, historically, described both the action of overeating (and more broadly overconsumption) and the excessive desires which caused overeating. In this way, gluttony describes both an action and its source. In describing an individual as gluttonous, the person’s

actions of overconsumption are traced back to a relatively simplistic picture of desire where one overeats because they desire food too much. The implication of this understanding is that actions of overeating always have a common origin in an excessive desire for food. For many, this understanding maligns the physical and psychological complexities which lie behind the actions of those who compulsively overeat.

Contemporary medical professionals researching eating disorders prefer the language of “compulsive overeating” to the language of gluttony. Research into bulimia (and also anorexia nervosa) has revealed that this eating disorder cannot be understood or reduced to overactive desires for food. Understanding eating disorders as merely excessive desires for food “completely ignores the reality of these conditions” (Johnson 2004). Psychologists have shown that eating disorders, by and large, stem from “a fragile sense of self and a core belief that life is uncontrollable” such that individuals with eating disorders use food and body weight as an “arena in which they can establish a feeling of control over their lives” (ibid). Understanding that the overconsumption of food found in certain forms of eating disorders stems from psychological states beyond merely an overactive appetite leads these researchers to jettison the language of gluttony. Labeling these eating disorders, variants of gluttony fails to capture the complexity of these conditions and perpetuates an anemic understanding of their cause(s).

Paralleling this move in the medical community, recovery programs aimed at helping individuals who are facing issues of overconsumption have jettisoned the language of gluttony in favor of “compulsive overeating.” Overeaters Anonymous (OA), a 12-step program modeled on the principles of Alcoholics Anonymous (AA), opted for their current name during their first national conference in 1962. At this meeting, participants rejected a proposal to call the emerging organization “Gluttons Anonymous” (A Step Ahead 2011). This choice of name typifies this organization’s understanding of gluttony. The compulsion to overeat is not the product of excessive desires for food but rather a myriad of psychological compulsions of varied origins. Sharing a common

view with other recovery organizations such as AA, OA members seek to identify the unique circumstances and compulsions which cause them to overindulge. For OA, it is not the case that similar indulgent actions shared among different individuals are indicative of a common and shared underlying cause, desire, or state of character. Each person who suffers from compulsive overeating does so for specific and unique reasons. Individuals in OA (in a way similar to people in AA) have chosen to distance themselves from the historically situated understanding of “gluttony,” preferring a more robust understanding of the actions of overeating which extends beyond the confines of the traditional discourse.

In this way, the medical, social, and moral landscape of gluttony has, again, changed. While the medical and social understandings of overconsumption have intentionally distanced themselves from the language and history of gluttony, the physical, medical, and ethical dimensions of health, compulsion, and responsibility remain. To some this might mean that gluttony, as a term and a concept, has become outdated, archaic, and useless (Su 2013). Yet to others it means that the moral and ethical issues surrounding gluttony have been, and need to be continually, expanded from its traditional roots into broader discussions of psychology, physiology, and addiction.

Summary

Dominant Western views of gluttony, and the assessment of gluttony as a moral failing, have undergone many changes. In Ancient Greek virtue ethics, gluttony was chided as the manifestation of errant desires and proclaimed a barrier for the achievement of the good life. The emergence of Christianity altered this view and transformed gluttony into a form of idolatry where gluttonous individuals are rebuked as having shifted focus from the divine to the sinful pursuit of worldly pleasures. Moral views of gluttony again shifted in the mid-nineteenth century and have become intimately tied to social views of fatness and body shape. As attested to by experimental psychology, gluttony has become the perceived cause

of fatness. The persistence of anti-fat biases have resulted in gluttony being identified as a moral failure which relates to unhealthy lifestyles and aesthetically displeasing body shapes. In addition to historical changes in understandings of gluttony, some have chosen to abandon the language of gluttony as a means for exploring the moral harms of overconsumption. Research into overeating as it relates to addiction and eating disorders shows that the language of gluttony fails to capture the psychological complexity of the compulsion to overconsume.

Introduction

Research on and development of genetically modified organisms (GMOs) has been facilitated by modern biotechnological techniques. The first GM plant, a tobacco plant expressing an antibiotic resistance gene taken from a bacterium, was grown in a greenhouse in 1983. Since then a

variety of GM crop plants have been released into agricultural fields. At present, herbicide-resistant crops are the most widely grown GM plants (approximately 70%). These GM crops contain genes that enable them to degrade ingredients in herbicides and imply that farmers can control weeds by herbicides as well as low tillage practices. Genes from the *Bacillus thuringiensis* have been inserted in plants to make them resist insect attacks and are the second most popular GM crops at the market together with plants that contain stacked genes, a combination of herbicide tolerance and insect resistance. At present, there are a huge interest and research initiated to achieve disease tolerance, altered compositions, stress tolerance (especially related to drought tolerance), as well GM plants that can be used to produce pharmaceuticals and be used for environmental remediation.

Applications of GMOs offer prospects for better human and/or animal health, food improvement, new ways for production of biofuel and fiber, as well as environmental protection. The cultivation of GM crops agriculture has, however, also been followed with concerns. Opposition and scepticism to GMOs has been especially prominent in Europe, where the introduction and use of GMOs have become subjects of scientific and public discussions and controversies. There are divergent opinions on whether GMOs and GM food are representing risks of adverse effects on health and the environment. Part of the controversy over GMOs may originate in the novelty of the genetic modification techniques, the time before health and environmental impacts can be assessed, and the differences in value commitments, ranging from safety to social and sustainability issues (Melo-Martin and Meghani 2008).

In this entry, the technology behind genetic modification will be described together with a brief presentation of innovations with an emphasis on new events and usage. Concepts for risk assessments and the main concerns for safety, health, and nutrition will be explained together with a brief discussion of the importance to include assessments of socioeconomic effects and the sustainability by the use and introduction of GM crops.

GM Plants and the Technology Behind Genetic Modification

From the very simple GM plants with only one inserted transgene, the world is now facing plants containing multiple genes from several different species, encoding not only the trait of interest but also genes that enable the plants to express different traits.

The technology in use involves the transfer of genes from, among others, microbes into plants and includes laboratory methods used to identify and isolate DNA fragments or genes from one organism and insert into a vector (usually a bacterial plasmid) and transfer of the vector combination into a host cell (usually with help from a gene gun or by injection). This has evolved from the simple insert of, for instance, one gene of a *Cry* protein (derived from the bacterium *Bacillus thuringiensis*) and to what today is termed stacked GM plants, containing several different genes expressing both insect resistance and different kinds of enzymes leading to resistance to several kinds of herbicides at the same time (de Schrijver et al. 2007). This innovation trajectory has been driven by the increasing development of resistance among pest insects as well as evolving development of resistance among weed towards the herbicides in use.

Herbicide Tolerance

The most used approach is the development of glyphosate-tolerant crops. Glyphosate kills plants by blocking the enzyme EPSPS, important for biosynthesis of aromatic amino acids. In the glyphosate-tolerant plants, one has introduced a technology into the plants, targeting key enzymes in the metabolic pathways of the plants, like the EPSPS enzyme, and made it glyphosate tolerant.

The cultivation of herbicide-resistant crops has become a challenge due to the development of herbicide-tolerant weeds. One solution to this has been to introduce genes that have other ways of detoxifying the herbicide (Benbrook 2009). Another option is to use a combination of herbicides to give a more effective treatment. The target protein of the herbicide can also be modified in

ways that in the end makes it unaffected by the herbicides used.

Pesticide Resistance

The second most used approach is development of insect-resistant crops, dominated with what has been termed Bt plants containing *Cry* protein from the bacterium *Bacillus thuringiensis*. The main targets are insect orders considered as pests in fields such as Lepidoptera, Diptera, and Coleoptera. When the insect ingests the *Cry* protein, the protein is converted to its active, toxic form. The toxin binds to receptors on the midgut epithelial cells, which subsequently are followed by development of pores in the cell membrane. The development of pores affects the regulations of osmotic pressure, and this disruption of the digestive system causes the insect to starve and eventually die.

The intention behind Bt crops is to avoid using chemical insecticides to control pests in agriculture. From the onset, there was a concern that Bt crops could harm nontarget insects and that target insects could develop resistance. Bt plants enable a constant exposure, potentially creating an evolutionary pressure for pest resistance to the toxin. Although management strategies have been implemented as refuges, areas surrounding the fields with non-Bt crops to facilitate nonresistant insects to survive and establish a susceptible population, pest insects have developed resistance (Gassmann et al. 2011). There are many different options when it comes to solving the upcoming challenges of resistance development. It has, for example, been identified around more than 100 different variations of Bt toxin that can be used in combinations to reduce the speed of development of resistance in pest insects. Other insecticidal compounds as defense proteins are also under investigation for being used in future insect-resistant plants.

Analogy to the History of Antimicrobial Resistance

The history of resistance development between weed and pests by cultivation of GM plants is starting to look like the history of development

of antibiotic resistance in pathogenic bacteria. With antibiotic resistance, the answer to the increase in resistance development has been to decrease the use of the causing agent – not to increase it. As it is now, the development of tolerant weeds and resistant pests is forcing farmers to increase their use of herbicides and pesticides as well as the use of multiple applications to overcome this evolving challenge. There is crucial need to consider new and more constructive ways of dealing with the development of tolerance and resistance. The problem will not disappear with the emerging stacked GM plants and herbicides and pesticides in use, unless there is a change in management practices.

Food, Feed, Fuel, and Fiber

In 2012, the most planted GM crop was GM soy (approximately 80 mill acres planted), followed by GM maize, cotton, and oilseed rape (ISAAA 2013). In addition, GM papaya and sugar beet are grown commercially in the USA and tomato and peppers in China. GM soy, maize, cotton, and oilseed rape are crops that can be used for different purposes as, for example, food, feed, fiber, and fuel. At present, most GM plants are used in food and feed around the world either as the plant itself or in processed form. GM cotton is used both for fiber and animal feed, while especially GM maize, soy, sugar cane, and oilseed rape are relevant as sources for producing bioethanol. Research has also been initiated with trees as GM poplars for pulp and biofuel production.

Innovation/New GMs

Future releases of GMOs may be plants that will be intentionally designed to be physiologically or nutritionally significantly different or contain a number of different transgenes (stacked events). Traits resulting in climate tolerance and enhanced benefits for the consumer such as better taste, longer shelf life, and increased nutritive value may be expected. The future of GM and innovation in plant improvement technologies

(agriculture) will be affected by the future needs of our increasing populations.

The food industry has already innovated new GM plants containing higher amounts of compounds that is heavily used in the food industry. This includes new traits for industrial processes as starch from GM potato and oilseed rape with changed content of fatty acids.

As a response to consumers request for more nutritious food, there are several initiatives using genetic modification for developing “functional food” with either higher levels of nutritious substances already found in plants (as fatty acids) or plants that produce substances not found in plants (as omega-3 fatty acids). The most famous example of GM plant with substances beneficial to human health is the Golden rice developed by Ingo Potrykus and colleagues. The Golden rice contains beta-carotene, a metabolic precursor to vitamin A. The intention behind the development of the Golden rice is to prevent vitamin A deficiency in especially Southeast Asian countries. The health and benefits of this rice addressed is, however, controversial. For example, it has pointed out that beta-carotene may increase the risk of cancer in smokers and asbest workers (Omenn et al. 1996). That the early version of the Golden rice produced to low amounts of vitamin A to even tackle vitamin A deficiency. New and improved versions of Golden rice have been made, but the bioavailability of vitamin A from these plants has also been questioned (Botha and Viljoen 2008). And as of today, Golden rice is still not commercialized.

At present, there are a huge interest and research initiated to achieve new GMs, and this also involves new approaches as using nanotechnology, RNAi technology, and synthetic biology that can be used separately or in combinations. Whether the introduction of new GMs and new technologies will translate into greater health and environmental risks than present is not clear.

Regulatory Frameworks

There is international law that covers regulation of GMOs, which includes the WTO (SPS and TBT)

and the Cartagena Protocol on Biosafety under the Convention on Biological Diversity (CBD). In addition, there is international soft law, made up of the emergent standardization on the level of protection together with the decisions taken by individual countries on risk assessment and risk management based on the precautionary principle among other things.

There are national laws, with some of the most marked differences between the USA and Europe. Regulation varies in a given country depending on the intended use of the products, and in general, GMOs can be notified for import and processing, for food, feed, and industrial use and/or cultivation. A GMO application can cover one or more of the different categories.

Europe

The EU has enacted some of the most restrictive rules when it comes to regulatory frameworks for GMO assessments, matched only by Norway’s GMO legislation. The biosafety regulatory framework follows the GMO development process from research in contained use to deliberate release and placing on the market; to labeling and traceability of GMOs as food, feed, or for processing; and to transboundary movement. Risk assessment in the EU is conducted via the European Food Safety Authority, EFSA, who coordinates scientific committees, which provide advice to decision-makers. The different regulations are the Deliberate Release Directive where the objective is the protection of human health and the environment, and it is based on the precautionary principle, and the GM food/feed regulation where the objective is the protection of human and animal’s health and the environment. It also ensures transparency, so that consumers are aware of the GMO content of a product. Further, the regulation on traceability objectives allows for the control and monitoring of GMO production and the marketing chain, and the regulation on transboundary movements (export and import) of GMOs in the EU implements the obligations under the Cartagena Protocol on Biosafety. It states that no export of GMOs destined for environmental release can be carried out by any European exporter without the advanced

informed agreement from the potential importing country.

Norway must in addition to the criteria of health and the environment heed the criteria of social utility and sustainable development. The purpose of the Norwegian Gene Technology Act (No. 38/1993) is to ensure that the production and use of GMOs take place in an ethically justifiable and socially acceptable manner, in accordance with the principle of sustainable development and without adverse effects on health and the environment. The ethical criterion as well as the wording on socioeconomic concerns of EU Directive 2001/18 may also have some opening for inclusion of issues beyond health and environment (EFSA 2011).

USA

The USA has far more GM crops on the market than any other nations, and their regulatory systems with respect to GM foods are organized under existing statutes design for invasive plants, chemical pesticides, and food additives. Hence, in the USA, the use of recombinant DNA techniques per se would not trigger any special regulatory consideration. These policy directives led to the doctrine that later became known as the “substantial equivalence” (Freese and Schubert 2004). The federal statutes that are used to regulate the products of agricultural biotechnology give primary jurisdiction to three agencies: the Food and Drug Administration (FDA), the Department of Agriculture’s (USDA) Animal and Plant Health Inspection Service (APHIS), and the Environmental Protection Agency (EPA).

In general, technical experts consider the safety of GM crops on a case-by-case basis in line with the concept of substantial equivalence. The substantial equivalence approach entails that the chemical composition and some biological characteristics of a GMO and its unmodified counterpart is compared with the purpose to identify if there are some relevant changes that need to be further assessed. Furthermore, the US risk-based regulation does not as the European regulation involve ethical and social factors in their risk evaluation.

Cartagena Protocol

The Cartagena protocol on biosafety is an international agreement that seeks to establish an international framework for safe management of all potential uses of GMOs (LMO is the term used in the protocol) that could affect biodiversity. The protocol, which is a supplement under the Convention of Biodiversity, went into force in 2003. The objective of the protocol is to contribute to ensuring an adequate level of protection under transboundary movement, handling and use of LMOs that may have adverse effects on the conservation and sustainable use of biological diversity. Risks to human health are also included. Moreover, the parties may take socioeconomic consideration arising from the impact on the conservation and sustainable use of biological diversity into account.

By March 2013, 166 countries have signed the protocol; however, the main producing countries as the USA, Canada, and Argentina are not at present signatories.

Risk Assessment

Genetically modified plants, such as crop plants intended for food and feed or release into the environment, have to undergo risk assessment prior to marked authorization in many countries. In most countries, governmental employees are responsible for the performance of regulatory risk assessments in accordance with international and national laws. In general, the safety assessment of GM food and feed should be assessed in a case-by-case basis, and it should not be possible to make general statements on the safety of all GM foods.

The main lines of arguments or principles applied in GMO assessments can be divided into three broad categories: environmental, health, and social concerns. When it comes to potential health risks associated with GM crops for human or animal consumption, concerns about increased resistance to antibiotics, toxicity, and allergenicity have arisen. In general terms, the safety assessment of GM foods should investigate toxicity, allergenicity, specific components thought to

have nutritional or toxic properties, stability of the inserted gene, nutritional effects associated with genetic modification, and any unintended effects which could result from the gene insertion (WHO 2002).

Antibiotic Resistance

Antibiotic resistance is a highly efficient tool for practicing GM techniques because it easily allows the scientist to identify the cells that are expressing the cloned DNA and to monitor and select for the transformed progeny. The selectable marker gene is usually co-transformed with the gene of interest and can therefore be transferred to other organisms. In the case of antibiotic resistance markers, there is a fear that the presence of these markers in GM crops could lead to an increase in antibiotic-resistant bacterial strains in general and that the antibiotic resistance genes should be transferred to a pathogen (VKM 2005).

While Norway, when assessing cases of antibiotic-resistant GMOs, bans the production, import, and sale of all GM products that contain genes coded for antibiotic resistance, the EU does not. Generally, selectable marker genes are not required, and methods are being developed to create marker-free plants.

Allergenicity and Toxicity

There has been an increased focus on health/toxic effects associated with not only the introduction of a foreign gene but also the effects associated with herbicides used with GM crop cultivation. Also, since the prevalence of allergic diseases has been increasing continuously, the question if GMOs exhibit increased allergenicity has been raised. There are studies today that show that GM crops do have the potential to cause allergenic reactions, due to the introduction of potential foreign allergens, to potentially upregulated expression of allergenic components caused by the modification process or to different means of exposure (Freese and Schubert 2004; Spöck et al. 2005).

In the EU, the assessment of the allergenic or toxicological potential is required for marked authorization of GM crops. However, very often the applications only contain arguments

supporting why the GM plant does not present any allergenic or toxicological risk, and no experimental work to assess the allergenic or toxicity potential of the GM plants is included. The most frequently used arguments for allergenicity assessment are “the source of the novel protein does not derive from a known allergen source, lack of sequence homology to known allergens, the novel protein can be easily digested, and the inserted gene is expressed at low levels.”

For toxicity assessment, the most frequently used argument is very often based on the general “weight of evidence approach” consisting of history of safe use, lack of structural or functional relationship to proteins that adversely affect human or animal health, low expression level of the protein in the grain, rapid digestion of the protein in mammalian simulated gastrointestinal fluids, and lack of acute toxic effect to mammals.

Very often, biotechnology companies do not test the transgenic protein actually produced in their engineered crops. Instead, for testing purposes, they make use of a bacterially generated (usually *E. coli*) protein that may differ from the plant produced one. Many of the posttranslational modifications (PTMs) differ between species, tissues, stage of development, and according to environmental variables such as temperature and light intensity which makes it important to test the transgenic protein actually produced in the engineered crops and not the surrogate protein (Gomord et al. 2005; Küster et al. 2001).

In order to scientifically address the potential health effects of a GM plant, it is necessary to have access to tests, preferably on mammals. Mammalian feeding trials have been usually but not always performed in applications in order to obtain commercialization for GM plant-derived food or feed (EFSA 2008). There is an ongoing debate regarding the necessary length of mammalian toxicity studies that should be included in a risk assessment before a GM plant product is released on the market for food/feed consumption.

There are many in vitro systems (such as usage of human cell cultures) that can be used to assess relevant risks regarding allergenicity and toxicity, testing in such systems not required today. In

addition, new methodological toolboxes, such as genomics, proteomics, and metabolomics, have been developed to cope with complex interactions, the cooperation and coordination of multiple genes, and the dynamics of total genomes. These developments opens up for new possibilities and will have future implications for biosafety assessment of GMOs (Heinemann et al. 2011).

The Precautionary Principle and Approach

The role of the precautionary principle and approach in risk assessment and management of GMO use and release is a subject for scientific and public discussions. There has been a shift in the debate from how to apply the precautionary principle into elaboration over what a precautionary approach might entail. A precautionary approach to GMOs requires a renewed look at the science underpinning risk assessment and management of GMO use and release and entails an awareness of that there is a difference between risk and uncertainty. This also implies that there is a need to identify practical means for a precautionary-oriented research design and to explore the role of precautionary motivated science in GM policy and research decisions.

Sources of Information

Most assessments and biosafety data are produced by the GMO applicant and submitted to the regulatory authority together with the technical details of the products as well as responses to other requirements, often with portions labeled as confidential business information (CBI). Data that are considered to be CBI (e.g., insert sequences, toxicology and allergenicity studies, environmental interaction) are not accessible and can therefore not be scrutinized by others than regulators (Nielsen 2013). With most of the data submitted by the companies to the regulatory authorities being considered as CBI, independent scientific studies concerning potential toxic effects/health risks of GM crops for animals or humans are severely lacking from the scientific literature.

As showed by Domingo (2007), few studies (most of them being short-term studies) have been conducted until now. In 2012, Séralini and coworkers published that herbicide-tolerant GM maize and the herbicide Roundup were toxic to rats. The controversy that followed this publication illustrates the need for long-term studies of health effects by GM consumption.

GM crops are grown in agriculture fields and may have impacts on biodiversity within the fields and in the surrounding. Some scientists have raised concerns regarding the spread of transgenes to wild or weedy relatives, the impact of GMOs on nontarget organisms, the accumulation of *Bt* toxins in the soil, and adverse impact of GMOs on insects (such as bees), nematodes, and birds, all of which either consume GMO seeds or their by-products or are present in glyphosate-saturated soils. These are all areas of concern where additional studies are needed to gain a fuller understanding.

In general, it has been argued that there is a need to achieve a more transparent assessment process, where it will be possible to get access to information and raw data as well as testing material. A more open process will also allow for testing and verification by other institutes and scientists and hence provide broader assessments of the risks and uncertainties involved.

Monitoring and Labeling

According the EU Directives, the applicant has to elaborate plans for post-market monitoring (PMM) of the GMO. The purpose of monitoring is twofold, firstly to confirm assertions made in the risk assessment regarding the occurrence and consequences of potential adverse effects by introduction of the GMO or its use, so-called case-specific monitoring, and secondly to identify the occurrence of unanticipated effects on health or the environment of the GMO, termed general surveillance monitoring. This is a challenging task, for example, at the European level, there are different regions and a variety of

agroecosystems with differing protection, environmental, and socioeconomic goals.

To monitor, one needs historical data that can only be provided by baseline information and indicators. Such data may relate to characteristics of agriculture practices, ecological conditions for farming systems, and ecosystem functions. In many countries, there are established environmental monitoring programs that may provide baseline information; however, unwanted health effects may be more difficult to identify. When monitoring for the health effects of a GMO, we have to know when, what, and how much of a GMO was eaten and for how long which means that exact labeling for all GMO components is important. And also, in order to systematically assess the impact of any GMO on health or the environment, one must be able to answer the questions, “is the GMO present in the material of interest?” and “how much of it is present?” which means that analytical methods are important.

To have an actual free choice on what you eat also involves that you know what you eat (Thompson 2007). One cannot identify GMO products barely by looking at it; thus, one is dependent on proper labeling to do an active choice. The concern for human and environmental health, animal welfare, and biodiversity has caused evolving demands for labeling of GMO products. Hence proper labeling is necessary for enabling consumer choice and for traceability in case of unforeseen effects. The EU has GM food and feed regulations that allow a threshold of 0.9% for presence of EU-authorized GMO in cargo or food and feed samples. In contrast to the EU, the USA has no GMO thresholds or obligatory GMO labeling. Industry should take an active part of this, especially since labeling in general of food products increases the trust of consumers towards food industry.

Sustainability and Socioeconomic Aspects

The issue of sustainability, social, and ethical aspects of gene technologies and the use of GMO is often a part of the national and

international debate. Some countries consider some of these aspects in their regulations and some not.

Recently, there has been an increase in interest in defining potential or observed socioeconomic impacts of GM crops. To get an improved understanding of socioeconomic aspects by producing GMOs, there is a need for identification of monetary and nonmonetary implications at farm and community level, impacts on sociocultural and institutional context of GM crop introductions, as well as elaboration of protection goals in relation to socioeconomic welfare.

The Brundtland Commission defined the concept of sustainable development in the following way: “Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED 1987).

In a report by Rosendal and Myhr (2009), it was found through an analysis of the scientific literature that very little experimental research has been carried out to identify how GM crops in practice affect sustainability and societal issues around the world. Accordingly, the author’s emphasis the need for research on how GMOs affect sustainability and socioeconomic aspects in countries that grow GM crops and in those that import GM-based products. Moreover, the scepticism against GM in food production within Europe has shown that consumer preference and acceptance are needed to be taken much more seriously (Thompson 2007). The cultural significance of food is closely attached to concepts as naturalness, religion, ethics, and tradition, which are societal aspects that need to have a much more important role.

Summary

GM plants and products are at present used as food and feed around the world. GM plants are also increasingly used for fiber and in biofuel. Most of the commercial varieties are developed to provide tolerance against herbicides and resistance against pest. There are initiatives for development of new GM plants that may have changed

nutritious value or other characteristics of interest for consumers. However, there are still unresolved questions with regard to potential risk to health and the environment. This has triggered a call for application of a precautionary approach as well as awareness to the broader issues as sustainability and socioeconomic aspects by introduction and use of GM plants. In the future, it is important that more broad assessments are carried out of GM plants; this is a responsibility that lies on the industry, on the scientific community, and on the governmental authorities.

GMO Food Labeling

Introduction

Genetically modified organisms (GMOs) are organisms made using recombinant DNA (rDNA) technology, also referred to as genetic engineering or gene-splicing. This technology involves using individual genes from a source organism to modify the living DNA of a target organism from a different species, which can be an animal, plant, or microorganism. Producers are thus able to overcome the species barrier, a natural limitation of traditional methods of

genetic improvement such as plant hybridization. First developed in 1973, transgenic techniques have been used to create disease-, pest-, and herbicide-resistant crops, faster-growing animals, and plants with enhanced nutritional properties (NAS 2010; Blatt 2008).

Countries vary widely in how GM food products are labeled and regulated. Over 40 nations currently require all foods with GM ingredients above a certain threshold to be labeled, including all European Union (EU) countries and most Asian nations. In Europe, transgenic crops can be planted only in very limited areas, and in most African countries, growing GM crops is illegal. Labeling is also mandatory in Australia, New Zealand, and Japan (Paarlberg 2010). But in others – most notably, the USA, Canada, and Argentina – labeling is voluntary and rare. In these countries, GM crops are widely grown, especially soy, corn, cotton, and rapeseed (canola). Over 80% of processed foods currently found on American grocery shelves contain ingredients derived from GMOs. However, surveys show that most consumers are unaware of the extent to which their food contains GM ingredients and the vast majority of consumers are in favor of mandatory labeling (Radas et al. 2008). This entry will discuss current policy and common arguments for and against GMO labeling.

Historical Background

In the 1990s, countries around the world first began approving GMOs for commercial use. Beginning in 1994, the US Food and Drug Administration (FDA) approved the Flavr Savr™ tomato, soon followed by the Monsanto Corporation's Roundup™ Ready soybean and its Bt versions of corn and cotton. Roundup Ready™ crops are engineered to resist glyphosate, the main ingredient in Monsanto's popular Roundup™ herbicide, and Bt plants have been modified to produce their own insecticides using a gene from a soil bacterium (Blatt 2008). Since the mid-1990s, the FDA has cleared many other crops. It is currently considering a proposal to allow the sale of genetically engineered salmon developed by AquaBounty which would grow much faster

than natural salmon. Through the early to mid-1990s, many other countries followed a similar regulatory trajectory: the EU approved several GM crops for commercial use while selected others were approved in Australia, Mexico, Japan, and Argentina (Thorpe and Robinson 2004).

Soon thereafter, countries began to diverge in their treatment of GM foods. The US and Canadian governments have continued on a supportive path and have consistently denied the need for the mandatory labeling of GM food ingredients. Food labeling in the USA is governed by the FDA, under the authority given to it by the federal *Food, Drug, and Cosmetic Act* (FDCA), with the exception of meat and poultry products which are overseen by the US Department of Agriculture (USDA). In 1992, the FDA announced that the fact that consumers might want to know whether a food had been produced using transgenic techniques did not justify mandatory labeling since it found no evidence that human consumption of biotechnologically produced food was unsafe (FDA 1992). Since the FDCA authorizes the FDA to prevent misleading labeling practices, implicitly this meant that in the agency's view, nondisclosure of GM content does not make a product's label misleading. At the same time, the FDA announced that GM foods can be marketed without independent testing unless they contain surprising ingredients, like a tomato containing a peanut protein, which could pose problems for consumers with peanut allergies. Companies seeking to market GM crops now participate in a relatively informal approval process called an FDA "consultation" in which they voluntarily present the results of their own testing to the agency. All GM foods and feeds currently available in the USA have undergone this review, as it is in the interest of producers to do so (McHughen and Smyth 2008). By and large, the Canadian government has taken a similar approach. As in the USA, GM foods need not be labeled as such, although in Canada manufacturers must submit data for pre-market review before GM products can be sold (Wohlers 2010).

The European approach has evolved to be quite different from the American model. Broadly,

whereas the US regulatory focus has been on the end product, the EU has focused more on process. Beginning in the late 1990s, the continent's previously more permissive attitude was replaced by a more conservative position. Guided by what is known as the "precautionary principle," the idea that in the absence of sufficient scientific evidence, potentially harmful activities should be treated cautiously, EU regulators need no specific evidence of risks to health or the environment to block a GM food from coming to market. All products with more than 0.9% GM content now must be labeled (Paarlberg 2010), and special requirements apply to GM foods which exceed the general "traceability" mandates that apply to all EU foods, food ingredients, and feed (EU 2007). Several things help to explain this comparatively cautious approach. The continent's experience with "mad cow" disease in the late 1990s heightened concerns over food safety, giving anti-biotech activists an opportunity to take advantage of consumers' fears. Also, Monsanto and US grain processors blundered in their first shipments of GM products to Europe by mixing GM and conventional soy together and sending the mixture to the continent unlabeled and unannounced. In response, European media started to give GMO foods significant coverage, leading to high consumer awareness of what soon became derided as "Frankenfoods." Some grocery chains gained market share by pledging to carry only GM-free foods, and others soon followed suit. Moreover, all of these events took place in a cultural and political context different from that found in the USA and Canada. Europeans have a long-standing cultural attachment to locally grown food, and agribusiness firms have less political clout in Europe than in North America. Whereas most farming in the USA is done by large-scale agribusinesses, in some areas, European farming remains comparatively nonindustrialized and family oriented (Schurman 2004).

Arguments for Labeling

The most common argument in favor of GMO food labeling is based on considerations of

consumer autonomy, often expressed in terms of the customer's "right to know." In general, personal autonomy is the right to make important decisions about one's life for oneself, free of deception and coercive influences, in light of one's values, goals, and conception of the good life (Brock 1999). The standard argument for GMO labeling is thus that respect for autonomy requires allowing consumers to decide for themselves whether to use products with GM ingredients, which is a decision consumers can make only if food manufacturers disclose the GM content of their products. Some authors have argued that so-called negative labeling – labels that state the absence of GM content – is equally respectful of consumer autonomy as positive labels that reveal the presence of GMOs (Hansen 2004). Also, negative labels effectively put the cost burden on consumers who desire information about GM food by enabling a price premium to be charged for non-GM products (Schmitz et al. 2010). Thus, negative labels are sometimes defended as a more fair way to allocate the costs associated with labeling and product differentiation. Current US standards require products labeled as "certifiably organic" to be GMO-free, which thus amounts to a kind of negative GMO label (Guthman 2003). Typically, however, consumer autonomy is used to argue for mandatory positive labeling.

The consumer autonomy argument is supported by numerous surveys over the years showing the vast majority of consumers in favor of required labeling. Recent studies by the Mellman Group and MSNBC found over 90% of American consumers supporting mandatory labels (Cummins 2012). Such results need to be interpreted with some care, however. At least in the USA, most consumers know little about GM-related issues, although this is not surprising given the relatively scant attention American media have given to the topic over the years. Consumer antipathy typically lessens when buyers are informed that they have likely been consuming GM products for years (Radas et al. 2008). Also, at present, most consumers see little personal benefit from GM foods. Currently, most of the gains from GM techniques accrue to

manufacturers and growers by way of reduced production costs (Schmitz et al. 2010). Consumers derive no additional nutritional benefit from most transgenic crops, since corn syrup, soy protein, and corn oil are the most common GM ingredients found in processed food (Blatt 2008). Their attitude becomes notably more positive when consumers are surveyed about GM techniques that enhance food quality, such as when they allow for the use of less pesticide or a longer shelf life or when they yield ingredients with enhanced nutritional benefits (Boccaletti and Moro 2000). Note also that there has been virtually no social resistance in developed countries to the use of genetically engineered recombinant medical drugs.

Especially early on, the consumer autonomy argument was commonly coupled with concerns about the safety of GM foods. Critics often point to the fact that GMOs rarely undergo independent safety testing. They also commonly allege some level of collusion between the US government and agribusiness firms in covering up harms, frequently citing the so-called revolving door that exists between government and the biotech industry (Smith 2008). Scattered reports of allergic reactions and other adverse events allegedly resulting from GM consumption also can be found. Thus, labeling is often advocated as a way for consumers to protect themselves. However, to date, the overwhelming scientific consensus is that GM foods are safe and "substantially equivalent" to their traditional counterparts, given that the changes brought about by genetic engineering usually fall well within natural ranges of biochemical variation. In fact, some scientists argue that GM crop varieties usually can be assumed to be safer than those that are produced by traditional breeding methods since GM technology targets isolated genes, leaving the rest unchanged, while traditional breeding sometimes produces unexpected changes (Spencer 2002). Regardless, since the 1980s, various distinguished scientific societies and organizations have pronounced GM crops to be safe, groups such as the National Academy of Sciences (NAS), the Royal Society of London, the French Academy of Sciences, the World Health Organization (WHO),

and the American Medical Association (AMA). Consequently, worries about the safety of GM foods are less prevalent than at one time. Still, comparatively few independent health studies have been conducted and those that have been done tend to be short-term studies involving small sample sizes (NAS 2004).

However, consumers often have reasons other than health for wanting to know whether or not their foods contain GMOs. They may be wary of GM products because for religious or other reasons, they oppose what they see as an attempt to “play God.” The fact that genetic engineering involves mixing genes from different species strikes some as disconcerting hubris. Other consumers worry about the long-range environmental effects of these technologies. Though in some cases the use of genetically engineered crops yields net environmental benefits, these effects may reverse themselves over time. For example, the advent of herbicide- and pesticide-resistant weeds and insects is a distinct possibility, particularly on farms where the same kinds of seeds and chemicals are used year after year (NAS 2010). Companies may be forced to continually introduce new varieties of organisms that can be sprayed with increasingly potent chemicals, resulting in a genetic engineering “treadmill.” Also, widespread GM farming means a loss of biodiversity, since GM techniques lend themselves most readily and efficiently to industrialized, mono-crop agriculture. Mono-crops are vulnerable to threats other than those that they have been engineered to resist (Blatt 2008). Other consumers are concerned about the privatization of agriculture that GM crops represent. Whereas seed used to be part of the commons, GMOs are patented forms of intellectual property. Growers’ contracts with seed companies require them to buy new seeds every year instead of saving seeds from the previous year’s crop, as is common in traditional farming practices (Shiva 2011). Monsanto in particular has sued numerous farmers for patent infringement when seeds from nearby GM crop fields end up in an unsuspecting farmer’s land, regardless of how they got there (Center for Food Safety 2010). Concerns about privatization are also fueled by the fact that agriculture is becoming increasingly

controlled by a small number of powerful, multinational corporations. GM techniques contribute to that trend. Lastly, some fear the effects of GM agriculture on nontarget species. Controversy has existed for some time regarding whether or not the insecticide produced by Bt corn kills monarch butterfly larvae, and genes from the same hybrid have found their way into native maize in Mexico (Kuzma et al. 2009).

Arguments Against Labeling

The most common argument against GM food labeling is that labels would not significantly enhance consumer autonomy and might needlessly scare people away from GM foods. This charge can take various forms. One complaint is that labels are unlikely to be specific enough to convey useful information. Labels announcing that a particular product “may contain genetically modified ingredients” might be largely ignored. Consumers who are concerned about the presence of some GM ingredients but not others would be poorly served by a generic label, and absent something more definitive, consumers may pay little heed (Spencer 2002). Requiring the labels to be more specific has its own drawbacks, however. For example, many processed food products contain highly refined oils derived from GM crops, but such oils typically lack any of the source organism’s DNA (McHughen 2002). A consumer trying to avoid ingesting genetically modified DNA would have no reason to forego these products, but most consumers are unlikely to understand these subtleties. The greater the amount of technical information conveyed, the more knowledge consumers need to make use of the information.

Another way to question the need for labels is to emphasize the difference between nutritional labeling and GM labeling. If it is assumed that GM foods are safe and healthy, then mandated GM labels require a rationale different from that used to justify current nutritional labeling requirements. Against this, though, current US label requirements demand more disclosure than is strictly speaking related to health and safety. Manufacturers must reveal the presence of artificial

flavors and colors, country of origin, and quantitative information about products, none of which are directly related to health (Streiffer and Rubel 2004). Critics of mandatory labels also compare the absence of GM labels to the absence of labels disclosing extraneous ingredients like hair fragments, animal excreta, and so forth (Spencer 2002). Such contamination is unavoidable, given the realities of modern food harvesting and processing. Yet the fact that the FDA does not require such information to be disclosed is not usually taken to be a violation of consumer autonomy.

GM labeling requirements also must resolve some practical difficulties. One problem is that of determining an adequate threshold for the distinction between GM and non-GM ingredients. Given the widespread sharing of grain elevators, transportation vehicles, and processing facilities and the reality of wind-blown seeds and insect pollination, it is virtually impossible to completely prevent non-GM fields from GM contamination. Some reasonable cutoff point must be decided upon, then, for the distinction between GM and non-GM to be viable (McHughen 2002). Relatedly, in order to be effective and meaningful, labeling requirements must be enforced. However, enforcement requires testing, and testing crops for GM content is expensive. Perhaps the most likely scenario is that non-GM producers would face increased costs resulting from validation procedures, costs that would almost certainly be passed on to consumers. The more difficult and costly it becomes for producers to certify their products as non-GM, the more likely they are to engage in rent-seeking behavior (Guthman 2003).

Summary

Given the multiple possible uses of genetic engineering and the variety of new organisms likely to be developed, labeling practices are likely to remain controversial for some time to come. Several nongovernmental organizations (NGOs) such as the Center for Food Safety, Greenpeace, and the Union of Concerned Scientists continue to push for tighter regulation of GMOs. In several states, legislation has been introduced to require

mandatory labeling and some members of Congress have supported pro-labeling bills for several years. To date, however, these efforts have had little effect. In 1996, Vermont voters passed a referendum to require labeling of dairy products from cows treated with recombinant bovine growth hormone (rBGH) which is used to increase cows' milk production. Following an appeal by Monsanto and the dairy industry, however, the law was struck down on First Amendment grounds. A 2002 ballot initiative in Oregon that would have required GMO labeling failed by a wide margin after agribusiness advertised heavily against it. A similar 2012 voter referendum in California was defeated after opponents of labeling outspent supporters by five to one.

Stepping back from such skirmishes, however, the debate about the labeling of GM food and GM technology itself illustrates a divide that reappears in many disputes about food and the environment. Those against mandatory labeling tend to regard genetic engineering as an extension and refinement of traditional breeding methods. For them, this technology is a means of solving important problems in agricultural production and the world's food supply by introducing foods with improved nutritional qualities or resilience to climate change and other vulnerabilities. Those in favor of mandatory labeling tend to regard genetic engineering more negatively. For them, this technology represents an unwelcome and unnecessary change in the relation between humans and the rest of the natural world.

Introduction

Since 2015, and as a result of the so-called “opt-out” Directive 412/2015 (EU 2015), the EU gives Member States (MS) the option to restrict or ban in all or part of their territory those genetically modified organisms (GMOs) that have obtained authorization for cultivation under Directive 2001/18/EC (EC 2001). To date, 19 of the MS (if we include the United Kingdom) have made use of this prerogative in all or part of their territory. If one contemplates this prerogative from a sociopolitical perspective, it is easy to associate its inclusion in EU legislation with the fact that the use of genetic modification in plants and in food and feed has since the 1990s been a subject that divides public opinion in MS. This is acknowledged by the European Commission itself in the documents explaining the aforementioned Directive (EU Commission 2015a). Decision-making in this area has been very much the exception to the usual functioning of EU comitology procedure as a whole, as can be observed in the data offered

by the EU Commission (2015a). Over the decades this division has created significant difficulties, deadlocks in particular, in the taking of decisions regarding GMOs within the community, and many voices have called upon the EU to reform GMO legislation in order to offer legal certainty to the different parties involved.

The *opt-out* clause that we are going to explain was introduced into the EU regulatory framework as a mechanism seeking to resolve this deadlock. In simple terms, we can say that this is a political and legal mechanism and it aims to reconcile two objectives which appear to clash: on the one hand, the EU's firm commitment to healthy and sustainable progress in biotechnology and, on the other, a certain space of autonomy demanded by certain MS vis-à-vis GM crops. The idea is simple, and the legal text containing this proposal seems simple too, but as will be shown, the practical application of this *opt-out* clause and its potential consequences present a mixed picture both for those who wish to make use of agrobiotechnology and for those in favor of reducing or excluding the use of GMOs in the EU agri-food sector. Which is why some authors refer to the introduction of the *opt-out* clause as a "way out of the regulatory impasse" (Salvi 2016) or, even, a "solomonic decision" (Escajedo San-Epifanio 2017b), which might lead in the near future to a another solution.

What Is an *Opt-Out* Clause?

As we know, the term *opt-out* clause applies to an exception or exclusion which the signatories of a contract (or of an international treaty) have included in the agreed text and which without threatening the final objective of the common make it possible for them to opt out of certain clauses or provisions (Villiger 1985). In a significant number of cases, as is evidenced by the history of international relations since the nineteenth century, acceptance of these reservations or *exclusions* has been understood as a means of making it easier, when there are discrepancies or differences between the negotiators, to reach an agreement.

Taking for granted that those who negotiate an agreement share a common interest in its

objective, it is easy to understand two things: why exclusion provisions can only be admitted as something exceptional and why the use of these clauses should not in practice compromise in any case the general purpose of the agreement. Without the latter safeguard, the agreement would lose all its value, given that signatories would have no guarantee that others would actually fulfil the commitments which they had assumed. For this reason, agreements that accept *opt-out* clauses explain in detail the circumstances in which their exercise is permitted and the mechanisms or limits which, even in the event of one of the signatories exercising their reservation or proposing a rare exception, guarantee that in general terms what has been agreed upon will be implemented (Villiger 2009). Thus, for example, Article 19 of the Vienna Convention on the Law of Treaties (UN 1969) indicates that when a signatory proposes a reservation or exception to a signed agreement, the remaining signatories have the right to accept or object to that reservation.

It may perhaps appear that Directive EU 412/2015 is not strictly speaking an *international agreement*, but as a matter of fact, it is. This Directive, which is part of the EU regulatory framework for GM crops, is an element of the agreements which at EU level have been adopted by MS in agri-food issues and, in turn, should be coherent with the principles upon which the MS have built their Union. Let us see what this *opt-out* clause consists of and what can be invoked for its application. Finally, we will also look at which ethical issues, grouped into three blocks, have yet to be resolved in the EU regulatory framework for GMOs, either because the clause does not address them or because they actually result from the clause itself.

The *Opt-Out* from GMOs in the EU: What Can Be Exempted and How?

The EU, as we know, traces its origins to the European Coal and Steel Community (ECSC) and the European Community (EEC) established in the 1950s by six MS (the so-called *Inner Six*). Since then the EU has expanded to 28 MS and has

evolved to the establishment of an internal single market through a standardized system of laws that apply in all MS, which has meant surrendering to the EU competences that were originally national (López-Basaguren 2017). Only with regard to some specific community policies do the Treaties include some *opt-out* options made available to MS either upon their joining the EU, or as a consequence of subsequent reforms (Holzinger and Schimmelfennig 2012). Altogether, these exclusions to EU Treaties are explained as exclusions, the objective of which is to avoid clashes between, on the one hand, EU legislation and, on the other, existing national laws in those countries (e.g., the UK's opt-out from the single currency or some specific exclusions from the EU Charter of Fundamental Rights). In these cases, however, countries that have exercised the *opt-out* clause with regard to some aspect of the treaties are not prevented from employing what is known as *opt-in*; thus, for instance, the UK and Ireland are in principle exempt from any legal act, agreement, or ruling related to policies of freedom, security, or justice but, if they so wish, may exercise an *opt-in* and occasionally adopt any measure which in that area of responsibility is adopted within the EU.

The *opt-out* clause included in Directive 412/2015 is truly exceptional (EESC 2015). The Directives are instruments of approximation to, or, more accurately, of harmonization with legislation, and in that sense, Directive 2001/18/EC includes an agreement between MS with regard to the requirements and procedure for authorization of GM crops throughout the EU. However, and here is the exception, with Directive 412/2015, a MS that has participated in decision-making vis-à-vis a GM crop may, following a crop's authorization, establish for its territory a total or partial exclusion. This is a mechanism without precedent. Important competences in questions of agriculture and food are now community competences, among them the decision as to which requirements must be satisfied by a GM crop in order for its possible uses (e.g., in agriculture, food, or industry) to be authorized in the EU as a whole. Particularly relevant among the agreements adopted is the creation by the *EU General Food Law* (EC 2002) of the European Food Safety Authority (EFSA), whose scientific advice helps

the EU and MS to protect consumers, animals, and the environment from food-related risks. However, and only with regard to GM crops, the EU has agreed that once a GM crop has passed the authorization process at EU level, strict risk assessment included, MS may, if they choose, exclude some of the effects which this authorization could have in their territory.

Explained with slightly more detail, in accordance with existing legislation, the authorization of the use of a GMO in agriculture or food remains fully harmonized at the EU level and is based on a single risk management system which the *EU General Food Law* (EC 2002) recognizes as the exclusive competence of EFSA. Consequently, the only change introduced by Directive 412/2015 is as follows: following authorization on a generic basis of the agricultural use of a GM crop, a period of time is established during which MS may express *compelling grounds* for restricting or excluding in their national territory cultivation of the crop in question. That said, according to the aforementioned Directive, the measures of exclusion or restriction proposed must be in conformity with Union law, reasoned, proportional, and nondiscriminatory and may be disputed if this is not the case.

This delimitation seeks to avoid misuse of the opt-out prerogative and guarantees that MS cannot exercise the latter in a manner affecting the objectives and commitments MS have assumed in the EU agri-food sector. Thus, what is clear here is the difference between the limited space afforded by the Directive for exercise of the *opt-out* from GM crops and some more radical proposals which certain sectors have been making in the EU within what is known as the movement in favor of *GMO-free regions* (Tosun and Shikano 2016).

The Use of Opt-Outs from GMOs in Practice: Measures That May Be Adopted and Compelling Grounds

Directive 412/2015 (EU 2015) makes the MS responsible for defining the measures they will adopt and the justification of their *opt-out* from GM crops authorized by the EU. Before the inclusion of this cause in decision-making on GM

crops, it was possible to express some individual concerns of democratically elected EU governments, for example, questions not based on science (EESC 2015) or other social considerations (CoR 2015), but applying Directive 2001/18/EC, the final decision could not be based on these. The *opt-out* clause incorporated in the new Directive is presented as a mechanism which, following the authorization of a GM crop in accordance with Directive 2001/18/EC, allows MS to take decisions within their territories regarding issues different from those addressed in this Directive.

The exercise of this *opt-out* prerogative, in accordance with Directive 412/2015, should be based on “compelling grounds such as those related to: (a) environmental policy objectives; (b) town and country planning; (c) land use; (d) socioeconomic impacts; (e) avoidance of GMO presence in other products without prejudice to article 26a; (f) agricultural policy objectives; (g) public policy.” The grounds may be invoked individually or in combination, with the exception of the ground (g) public policy which cannot be used individually, depending on the particular circumstances of the Member State, region, or area in which those measures will apply. In any case and lest there were any doubt, it is clearly indicated that the use of the prerogative should be based on *criteria other than those assessed by the EFSA at EU level*. Because this institution performs a crucial function in independent scientific assessment of food quality and safety in relation to the EU food chain as a whole.

The grounds on this list, essentially, are a transcription of Article 36 TFEU (EU 2007) of Directive 412/2015 (EU 2015). Thus, an initial consideration to bear in mind is that Article 36 TFEU itself, in its final clause, indicates that such prohibitions or restrictions shall not, however, constitute means of arbitrary discrimination or a disguised restriction on trade between Member States. It should not be regarded therefore that, in order to exercise the *opt-out* in relation to GMOs, these requirements are also included: in conformity with Union law, reasoned, proportional, and nondiscriminatory. Meanwhile, and turning to the list of compelling grounds of the Directive, the list’s wording basically coincides with Article 36 TFEU, which establishes the

possibility of introducing prohibitions or restrictions on imports, exports, or goods in transit “justified on grounds of: public morality, public policy or public security; the protection of health and life of humans, animals or plants; the protection of national treasures possessing artistic, historic or archaeological value; or the protection of industrial and commercial property.”

One of the few differences is that the Directive – unlike Art. 36 TFEU – leaves no *opt-out* margin to Member States based on the criterion of “protection of health and life of humans, animals, or plants.” In a resolution of January 13, 2015 (EP 2014), during the drafting of Directive 412/2015, the European Parliament requested that environmental grounds be among the reasons which Member States could use to justify their cultivation bans (EPRS 2015), but this was not accepted by the Council, which deemed it to belong to the risk assessment tasks of EFSA. Consequently, in the terms in which the Directive was approved, environmental questions that could be alleged will have to differ from those related to risks and shall in no case conflict with the environmental risk assessment carried out (at EU level) pursuant to this Directive or to Regulation 1829/2003 (EC 2003a).

With the exclusion of scientific-technical risks, the grounds that can be employed to justify measures restricting the use of GMOs focus, as a whole, on socioeconomic and environmental considerations. It should be borne in mind, however, that the ECJ has been interpreting narrowly the list of restrictions in Art. 36 TFEU, tending to accept almost exclusively those measures which are considered to be related to noneconomic interests, and it remains to be seen what stance it will take with regard to *opt-out* requests vis-à-vis GMOs (Escajedo San-Epifanio 2017b).

Ethical Issues (1): What Is the *Opt-Out*’s Contribution to the Controversy over GM Crops in the EU?

The GMO *opt-out* is a one-off measure which aims, in some way, to address a problem that has been affecting the EU since the 1990s. The EU was one of the first regions in the world to

establish a regulatory framework for GMOs. In the 1990s different measures were adopted (including Directives 90/219 and 90/220/ECC – see EEC 1990a, b), result of a participatory process in which from the late 1970s onward all the sectors involved met and compared, among other things, public and private research in the fields of molecular biology, plant biology, ecology, and population biology (Escajedo San-Epifanio 2017a). Since then, the EU has been making significant budgetary contributions to research and development both in agrobiotechnologies as a whole and, specifically, in improving knowledge with regard to the risks associated with these and the best ways of dealing with these risks.

The fact is that since the early 2000s it has been evident that the development of agrobiotechnologies in the USA, both in comparison with other reasons and with regard to the development of biotechnology in non-agri-food sectors, has revealed major shortcomings. An accumulation of political and economic factors was hindering research and development, especially with regard to the use of GMOs in agriculture and food. According to several trading partners of the EU in the WTO, the rate of commercial cultivation of GMOs in the EU was virtually nonexistent, and three *types of conduct were hindering imports of agrobiotechnological products*: authorization applications for new products were not being processed, unreasonable delays were occurring in the finalization of some applications already in process, and some Member States had banned in their territory already approved GM products availing themselves of safeguard clauses (see Bodiguel and Cardwell 2010; WTO 2006, 2010).

After that crisis, a second regulatory framework was introduced for GMOs in the EU, revolving around Directive 2001/18/EC on deliberate release (EC 2001) and Regulations EC 1829/2003 and 1830/2003 on GM food and feed and its labeling and traceability (EC 2003a, b). This legal framework is to be interpreted in the context of the *EU General Food Law* (EC 2002), which basically establishes the criteria of quality, safety, and consumer protection for the entire EU agri-food market and creates the European Food Safety Authority (EFSA).

Directive 2001/18/EC (EC 2001) harmonizes the national legislation on GMOs in the 28 EU Member States in compliance with the precautionary principle and aims to ensure that individuals and companies take necessary measures to safeguard the environment and human health prior to intentionally releasing into the environment a GMO or placing in the EU market a GMO or GM product. After the scientific evaluation by the EFSA, the MS – assisted by the European Commission – have to adopt a final decision for the EU as a whole. Systematically, however, the result of that final decision has been a *non-decision*, leading to a de facto deadlock in decision-making processes with regard to GMOs. The *opt-out* incorporated into the EU regulatory framework for GM crops with Directive 412/2015 seeks to avoid that final deadlock (or nondecision) differentiating between the decision to authorize a GM crop, which on the basis of EU criteria is maintained at EU level, and the decision which MS may later adopt vis-à-vis the agricultural use of that crop within their territory.

Barely two years after the adoption of Directive 412/2015, the question arises as to whether it will in fact lead to a substantial change vis-à-vis the deadlock that has existed for over two decades with regard to decision-making on GMOs at EU level. Under this Directive, 19 MS have implemented partial or total restrictions in their territory (Poli 2015; Romero Caro 2017), but, at the date of publication of this entry, decision-making at EU level is still deadlocked as exemplified by a voting on two GM maize events early in 2017.

Ethical Issues (2): Can MS Extend the Opt-Out to Commercialization?

The authorization process of GMOs in the EU permits the establishment of a specific use for which authorization is granted, excluding others such as agricultural use. In fact, in 2015 69 GM varieties were authorized for different uses in accordance with Directive 2001/18/EC, but among these uses, only six varieties could be cultivated. This leads to a kind of paradox,

which is particularly significant: a product may lack authorization for cultivation in the EU and, however, have no restriction upon its commercialization in the internal market (Escajedo San-Epifanio 2017b).

As one might imagine, the MS that expressed a desire to restrict GMOs in their territories also requested some kind of measure in order to restrict their commercialization, and this request was addressed by the Commission with a proposed reform of Regulation EC 1829/2003 (European Commission 2015b). This proposed amendment of Regulation EC 1829/2003 to introduce national restrictions on trade in GMOs was, however, overwhelmingly rejected by the EU Parliament (by 619 votes to 58, with 13 abstentions) (EPRS 2015), the Agriculture and Fisheries Council, the European Economic and Social Committee (EESC 2015), and the European Committee of the Regions (CoR 2015), as well as by the stakeholders of the EU food and feed chain and various NGOs.

The reason for the rejection, nonetheless, was not the content but the form of the proposal, in other words the way in which the reform was worded, its incompatibility with the agreements upon which the single market had been built in the Treaties (González-Vaqué 2017). It is foreseeable, therefore, that in the future there will be further proposals of this nature.

Ethical Issues (3): Are We Moving Toward Appropriate Development of Biotechnologies?

Almost 180 States represented in what came to be known as the *Earth Summit* (United Nations Conference on Environment and Development, Río de Janeiro, 1992) highlighted the importance for the Earth's survival of achieving an *essential balance* between economic, social, and environmental interests. This required, as was reflected in the commitments adopted, a transformation of forms of production, consumption, life, and relations, and in this desire for transformation, there was also a place for modern biotechnology. Biotechnology by itself, reflected in *Agenda 21*

(UN 1992), cannot solve all the fundamental problems of environment and development, but nevertheless it “promises to make a significant contribution in enabling the development of, for example, better health care, enhanced food security through sustainable agricultural practices, improved supplies of potable water, more efficient industrial development processes for transforming raw materials, support for sustainable methods of afforestation and reforestation, and detoxification of hazardous wastes. Biotechnology also offers new opportunities for global partnerships, especially between the countries rich in biological resources (which include genetic resources).” Hence, in the definition of its program areas and activities, *Agenda 21* (UN 1992) specifically included the need to “establish(ing) enabling mechanisms for the development and environmentally sound application of biotechnology” (Escajedo San-Epifanio 2010).

According to the Agenda, environmentally sound management of biotechnology will contribute to improved availability of food, feed, and renewable raw materials, by using the combined resources of modern biotechnology and conventional plant/animal/micro-organism improvement, including the more diverse use of genetic material resources, both hybrid and original.” But there are also challenges to be faced if we want to adequately balance the needs of farmers, the socioeconomic, cultural, and environmental impacts of modifications, and the need to promote sustainable social and economic development. EU MS do not share the same vision regarding hardly any of the elements to be balanced, and neither do they appear to agree over how to manage the coexistence between new and traditional agricultural techniques (Escajedo San-Epifanio 2017b). Thus, although it is very important to implement mechanisms that ensure coherence across EU legislation and policies directly regulating, or indirectly impacting on, the development of biotechnology, there is currently a risk that biotechnology will continue to suffer indecision or short-sighted and local solutions in the EU (EU Commission 2002). In fact, acceptance of the use of the *opt-out* clause regarding agricultural use of crops based on “criteria other than those

assessed by the EFSA” (EU Commission 2015a) appears even to increase the potential for a fragmentation of the situation.

In view of this situation, there are many voices in the scientific community who wonder what is different about GM crops which justifies the EU having accepted significant differences in their treatment compared with non-GM crops (Rosendal 2005). Furthermore, and with that debate yet to be resolved, scientific and technological development has given rise to new plant breeding techniques (NPBTs) which make it possible to modify the genomes of plants more precisely than via previous techniques and which are not easily accommodated within current EU Agricultural Law. If they stand out, moreover, from transgenesis, it is because they do not introduce into organisms foreign DNAs (vid. Sprink et al. 2016; Shiemann and Hartung 2015), which is one of the main reasons why some citizens and stakeholders, such as certain environmental organizations and the organic farming movement, reject the use of GMOs. NPBTs are being directly affected by the situation of uncertainty surrounding GM crops (Casacuberta et al. 2017), while it is striking that some techniques that are similar but applied to other organisms – even to human biological material – are hardly being debated. The EASAC (European Academies Science Advisory Council 2015) issued a statement requesting that the EU policy development for agricultural innovation should be transparent, proportionate, and fully informed by the advancing scientific evidence and experience worldwide, suggesting, on the one hand, a review, in light of new knowledge and experiences, of some political decisions adopted since the 1990s, and, on the other hand, demanding the resolution of current legislative uncertainties which affect agrobiotechnology.

Summary

In the year 2015, via modification of Directive 2001/18/EC, the EU incorporated into its GMO regulatory framework a new element: the prerogative of Member States to exercise an *opt-out* from cultivation of GMOs. To date, 19 of the

28 MS (including, for the time being, the United Kingdom) have made use of this prerogative in all or part of their territory.

This encyclopedia entry explains how and why this opt-out prerogative was introduced into the EU Regulatory Framework for GMOs, as well as its scope and the way in which EU Member States can make use of it. Next, and in three separate blocks, there is consideration of the ethical issues which arise from this reform of GM crops legislation in the EU regulatory framework for GMOs. Firstly, what is this opt-out clause’s contribution to the situation of controversy surrounding GM crops in the EU? Secondly, what is the possibility that this opt-out mechanism might (or might not) extend to commercialization? And thirdly, and lastly, following the adoption of this clause, what is the scenario for the development of agrobiotechnology in the EU?

Introduction

The controversy over genetically modified [GM] organisms is often framed in terms of possible hazards for human health. Entries in a previous volume of this *encyclopedia* give a general overview of GM crops (Mulvaney 2014) and specifically examine human health (Nordgard et al. 2014) and label (Bruton 2014) issues surrounding GM organisms. This entry explores several other aspects of the controversy: environmental concerns, political and legal disputes, and the aim of “feeding the world” and promoting food security. Rather than discussing abstract, hypothetical GM organisms, this entry explores the consequences of the GM organisms that have actually been deployed in the particular contexts that they have been deployed, on the belief that there is little point in discussing GM organisms in an idealized or context-independent way.

Background

“Genetically modified” is sometimes regarded as an ambiguous term. A plant or other organism might be called genetically modified if it is

artificial, that is, it has some of its traits as the result of an intentional human process. Nearly all commercially cultivated organisms are artificial, and humans have been producing artificial varieties of plants and animals (and fungi and bacteria) since the beginnings of agriculture. Alternatively, we might call an organism genetically modified if it is *genetically engineered*, that is, if it has been produced using techniques for the direct, molecular manipulation of its genome (or epigenome). More specifically, we could reserve the term “genetically modified” for *transgenic* organisms. These organisms contain a gene or gene complex from another species. For example, *Bacillus thuringiensis* [Bt]- or insect-resistant [IR] crops are plants that contain genes from a bacterium *Bacillus thuringiensis*. When people worry about “GMOs,” generally they are worried about either genetically engineered or specifically transgenic organisms, especially plants and animals. Since the majority of commercially grown genetically engineered organisms today are transgenic, these two terms – while conceptually or logically distinct – are often extensionally equivalent. However, non-transgenic but genetically engineered organisms are at the center of some emerging regulatory controversies in the United States and EU. Thus, in what follows, when this entry refers to GM organisms, this entry will mean organisms that are either genetically engineered or transgenic, not merely organisms that are the result of an intentional human process.

Globally, in terms of area under cultivation, about 59 % of GM crops are herbicide tolerant [HT], 15 % are Bt, and 26 % are stacked, combining both HT and Bt. Other traits combined account for less than 1 % of the use of GM crops. About 47 % of GM crops are HT soybeans; maize (corn) makes up about 32 %; cotton is about 14 %; and canola is about 5 %. Other species combined make up less than 1 % (James 2012, Table 41). On November 19, 2015, the US FDA approved the commercial sale of a GM animal, the AquAdvantage salmon. Until that point, all of the multicellular GM organisms that were approved for sale in the United States were plants.

Environmental Concerns

There are several categories of potential environmental concerns arising from the deployment of GM organisms as food: (1) evolution of herbicide-tolerant and pesticide-tolerant plants and animals, (2) transmission of genes (outcrossing, gene flow) from GM crops to wild weedy relatives and to conventional crops, (3) increased use of herbicides and pesticides, and (4) direct and indirect effects on other species and ecosystems.

Prior to the development of HT GM crops, it was known that weeds naturally varied in their response to herbicides such as glyphosate, with some very susceptible and others less so (i.e., some were naturally tolerant). Similarly, it was known that “pests” like the western corn rootworm naturally varied in their response to pesticides like Bt. Thus, it could have been predicted – and was predicted – that the widespread use of herbicides and pesticides in conjunction with GM crops would act as a selective agent, killing the susceptible ones and in effect selecting for the tolerant ones, allowing the tolerant ones to flourish without competition. Indeed, this is what has happened. In 2012, the Weed Science Society of America website listed 22 Roundup-resistant weed species in the United States; Dow AgroSciences estimates that 100 million acres in the United States are already impacted by Roundup-resistant weeds (Benbrook 2012). Similarly, western corn rootworms have evolved Bt resistance from their consumption of Bt corn (Gassmann et al. 2014). Thus, one environmental effect of the deployment of GM crops has been the evolution of herbicide-tolerant and pesticide-tolerant plants and animals. Some argue that this effect occurred because farmers failed to follow Monsanto’s recommendation to plant “refuges,” i.e., areas without GM crops. Refuges allow non-tolerant weeds/pests a place to flourish where they can interbreed with, and thus dilute the numbers of, tolerant weeds/pests. Recommendations call for 5–20 % of the total land to be set aside as refuges, depending on the GM crop. However, blaming farmers for the evolution of weed/pest tolerance may not be taking into account the financial and practical contexts in

which they find themselves; planting refuges means not only that farmers have to make a special effort to obtain non-GMO seeds but also that they have to forgo short-term profits in favor of long-term ones.

Herbicide-tolerant weeds can also result from a different mechanism that has its origin in GM crops. When GM crops reproduce with closely related wild species, transfer of herbicide tolerance to weeds can occur. Susceptible species include alfalfa, canola, sugar beets, and corn. Roundup Ready wheat (not on the market yet) was found to be six times more likely than non-GM control lines to produce outcrossed offspring (Rieben et al. 2011). These “transgenic weeds” could become difficult to manage and possibly invasive (Greene et al. 2015). Similarly, there can be transmission of genes from GM crops to other conventional (either non-GM or organic) crops. In a 2014 survey of 268 organic and non-GMO farmers in the United States, 31 % said that they had found or suspected GMO presence in their crops. Of these, 52% said that they had been rejected by a buyer because of it (Food & Water Watch and Organic Farmers’ Agency 2014). In Oaxaca, Mexico, one of the places where diverse strains of maize are found, researchers found “a high level of gene flow from industrially produced maize towards populations of progenitor landraces” (Quist and Chapela 2001). This is concerning because these maize strains might otherwise be used to create new commercial corn varieties; thus gene flow is affecting what might be considered a maize gene repository.

Increased herbicide tolerance, regardless of the mechanism that produced it, has led to an increased use of herbicides, even though one of the promises of GM crops was that they would reduce the use of herbicides. According to Charles Benbrook (2012), Roundup-resistant weed phenotypes are forcing farmers to increase herbicide application rates, make multiple applications of herbicides, and apply additional herbicide active ingredients. This is particularly significant in light of the World Health Organization’s classification of glyphosate as “probably carcinogenic to humans” and thus possibly carcinogenic to other

species as well. Moreover, Dow has used evolution of Roundup-resistant weeds to argue for the deregulation of 2,4-D corn. 2,4-D is considered a more toxic herbicide, with a heightened risk of birth defects, more severe impacts on aquatic ecosystems, and more damage to nearby crops and plants (Benbrook 2012). On the other hand, the use of Bt corn has led to a reduction in pesticide use so far, but given the evolution of Bt-tolerant pests (noted above), this reduction may be short lived.

As with humans (see Nordgard et al. 2014), there is currently no generally accepted evidence that animals that consume GM crops suffer direct health-related harms; more precisely, there is some laboratory evidence that Bt corn harms monarch butterflies (Losey et al. 1999), but no field evidence (Sears et al. 2001). However, AquAdvantage salmon – the first FDA-approved genetically engineered animal intended for food – creates the potential for another type of direct environmental harm. AquAdvantage salmon have been modified to grow at a faster rate (approximately twice as fast) than their non-modified counterparts, allowing them to be brought to market more quickly; critics have raised concerns about possible effects on other salmon, species that interbreed with salmon, and ecosystems more generally if the GM fish were to escape into the wild. Harm could occur, for example, if escaped AquAdvantage salmon or hybrids were considerably fitter than their non-GM counterparts – in a worst-case scenario, acting as an invasive species (Devlin et al. 2004). According to the FDA, precautions have been taken to prevent this:

The AquAdvantage Salmon may be raised only in land-based, contained hatchery tanks in two specific facilities in Canada and Panama. The approval does not allow AquAdvantage Salmon to be bred or raised in the United States. In fact, under this approval, no other facilities or locations, in the United States or elsewhere, are authorized for breeding or raising AquAdvantage Salmon that are intended for marketing as food to U.S. consumers. . . the AquAdvantage Salmon are reproductively sterile so that even in the highly unlikely event of an escape, they would be unable to interbreed or establish populations in the wild. (US Food and Drug Administration 2015)

Such precautions, supporters say, make any negative ecological consequences “virtually impossible” (Rack 2015). But it is widely acknowledged that a certain small percentage of the salmon will not be sterile (thus, the need for other sequestration methods). And once again, as in the case of Roundup Ready products, arguments in favor of GM deployment are assuming ideal conditions rather than the likely less-than-ideal conditions that can result from human error or unforeseen situations. Also, note that the FDA regulations do not and cannot prevent other countries from taking fewer precautions for AquAdvantage salmon sold in non-US markets. Thus, despite precautions, there is some potential for direct harms from GM animals intended for consumption; although it is not the focus of this entry, similar concerns may be raised about GM animals modified for other purposes, such as mosquitos modified to reduce the spread of dengue or malaria (e.g., the consequences of the loss of a species of mosquitos from an ecosystem or the spread of lethal genes to related species).

Finally, there is some evidence of indirect harms to other species as a result of GM crops. One type of indirect harm includes possible impacts on populations of species that depend for survival or reproduction on the pests controlled (Wolfenbarger and Phifer 2000). A second type of indirect harm is exemplified by the increased spraying of Roundup that has led to a loss of milkweed habitat for monarch butterflies and contributed to a major decline in the size of their populations (Pleasants and Oberhauser 2013). A third type of indirect harm is due to the fact that Roundup Ready corn seed is coated with neonicotinoid pesticides; neonicotinoids have been shown to affect bee reproduction (perhaps contributing to “colony collapse disorder”) and to persist and accumulate in the soil (Goulson 2013). Although these claimed effects are somewhat controversial, neonicotinoids have been temporarily banned in the European Union, and the USA’s Environmental Protection Agency (EPA) says that it is “unlikely” to approve new outdoor neonicotinoid-pesticide uses without new data (Cressey 2015). Indeed, in January 2016, the EPA classified the neonicotinoid imidacloprid as

very highly toxic to honey bees, citing effects such as reduction in number of worker bees available for foraging, reduction in foraging efficiency via sublethal effects on workers, decreased number or delayed development of brood either from direct exposure or indirectly from reduced brood feeding and maintenance by hive bees, and reduced fecundity and survival of queens.

Political and Legal Concerns

Especially in North America, many of the political and legal concerns surrounding GM crops stem (pun intended) from the control that intellectual property [IP] rightsholders enjoy over their use. In the United States, new plant varieties can be protected by two different kinds of IP rights. Sexually reproducing and tuber-propagated plants may be protected by a plant variety certificate under the Plant Variety Protection Act of 1970. This law contains exemptions that allow farmers to save seed and allow researchers to conduct research. General utility patents provide much more robust protection and control; the impacts of general utility patents on seed-saving and research will be discussed below. In the 2001 case *J. E. M. Ag Supply v. Pioneer Hi-Bred*, the US Supreme Court affirmed that GM plants are eligible for general utility patents (Janis and Kesan 2002).

It is also important to recognize that since the 1980s, public funding for agricultural research in the United States has been roughly flat, while private funding has roughly doubled (Fuglie and Toole 2014, Figure 1; see also Pray and Fuglie 2015). At the same time, at least one pair of researchers has argued that expanded intellectual property rights for GM plants have contributed to consolidation among plant biotechnology firms (Marco and Rausser 2008). A recent analysis of plant IP finds that the vast majority of certificates and patents are issued to a small number of large companies. In particular, DuPont “holds more gene patents than Monsanto or the rest of the US industry ... put together” (O. A. Jefferson et al. 2015, p. 1140). All together, these trends suggest that researchers and farmers are both more

dependent on multinational seed-biotechnology firms than in the past.

The Schmeiser Case

One common concern about GM crops is that agricultural biotechnology giants – especially Monsanto – routinely use their intellectual property rights to sue farmers. The basic worry here is that farmers face expensive lawsuits, financial liabilities, and (in the case of organic farmers) loss of organic certification, even in cases of “accidental contamination,” where GM seeds grow as weeds on farmers’ land. More generally, the concern is that intellectual property rights attached to GM crops give large corporations significant economic power over farmers.

These concerns frequently trace back to the Canadian case *Monsanto Canada v. Schmeiser*. Percy Schmeiser is a conventional (nonorganic) canola farmer in Saskatchewan. In the 1990s, Schmeiser routinely saved seeds from one year to use in planting the next year’s crop. Somehow – Schmeiser claimed it must have been accidental, but the point was controverted by Monsanto – GM canola that was resistant to Monsanto’s herbicide glyphosate (Roundup) came to grow on Schmeiser’s land. Schmeiser identified the herbicide-resistant canola through a series of sprayings and plantings, and by 1998 nearly all of the canola growing on Schmeiser’s land was Roundup resistant. Based on the fact that Schmeiser had saved and replanted patented seed, Monsanto sued for patent infringement in 1998. The Federal Court of Canada decided in Monsanto’s favor in 2001 (2001 FCT 256), and this judgment was upheld by the Canadian Supreme Court in 2004 (2004 SCC 34).

Monsanto and its defenders argue that the Schmeiser case does not provide a precedent for accidental contamination lawsuits. First, while it is not clear how the GM canola first came to grow on his property, nor what his ultimate intentions were, it is clear that Schmeiser was deliberately cultivating it: several times over, he sprayed a plot of land with glyphosate and then saved and replanted the seeds from the plants that survived.

Monsanto’s complaint was that Schmeiser identified, saved, and replanted the GM canola, not that it first appeared on his property by accident. As the Federal Court of Canada judge put it in her ruling, Schmeiser’s “infringement arises not simply from occasional or limited contamination of his Roundup susceptible canola by plants that are Roundup resistant. He planted his crop for 1998 with seed that he knew or ought to have known was Roundup tolerant” (2001 FCT 256, at 125). Saving and reuse, not accidental contamination, was also the issue in *Bowman v. Monsanto* (USC 2010–1068), a similar case in the United States.

Second, Monsanto has stated on several occasions that it will not sue farmers in accidental contamination cases. “Monsanto’s Commitment: Farmers and Patents,” a document on the company’s website, states that “It has never been, nor will it be Monsanto policy to exercise its patent rights where trace amounts of our patented seed or traits are present in farmer’s fields as a result of inadvertent means” (“Monsanto’s Commitment: Farmers and Patents” 2015). In 2013, Monsanto used this argument to defeat a class-action lawsuit from a group of organic farmers, who were concerned that Monsanto might sue them for patent infringement in the future (*Organic Seed Growers and Trade Association et al. v. Monsanto Company* et al. USC 2012–1298).

However, there are reasons why some people might still have concerns about accidental contamination and other patent infringement lawsuits. First, “Monsanto’s commitment” is not legally binding on Monsanto, much less any other large agricultural biotechnology company (compare Ma 2012, p. 716). Second, the rulings in Schmeiser’s case rejected arguments that would likely be used by defendants in accidental containment suits. For example, Schmeiser attempted to argue “that there was no intention to infringe the patent” (2001 FCT 256, at 115). However, the Federal Court of Canada judge found that:

it is well settled that infringement is any act which interferes with the full enjoyment of the monopoly rights of the patentee.... Further, intention is immaterial, for “infringement occurs when the essence of an invention is taken,” regardless of the intention of the infringer. (2001 FCT 256, at 115; see also Ma 2012, p. 703)

Schmeiser also attempted to argue that because the 1998 canola crop was never sprayed with Roundup, he “did not make use of the invention as the inventor intended and so, did not use the patented gene or cell” (2001 FCT 256, at 121). In response, the judge argued that:

In my opinion, whether or not that crop was sprayed with Roundup during its growing period is not important. Growth of the seed, reproducing the patented gene and cell, and sale of the harvested crop constitutes taking the essence of the plaintiffs’ invention, using it, without permission. In so doing the defendants infringed upon the patent interests of the plaintiffs. (2001 FCT 256, at 123)

In other words, the conditions under which the GM crops were grown are irrelevant. Merely growing patented plants might be sufficient for a successful infringement suit, if Monsanto or another rightsholder someday decides to start filing accidental contamination suits. (For an argument in favor of allowing unintentional infringement suits, see Janis and Kesan 2002.)

Furthermore, when it comes to deliberate infringement cases – cases where a farmer has signed a license agreement with Monsanto but saved seed anyway – critics argue that Monsanto uses excessively heavy-handed and intimidating tactics. The Center for Food Safety, a nonprofit organization that is opposed to GM crops, claims that “Monsanto investigators have taken samples from farmers’ lands without permission and without notice, have staked out farm supply store owners’ property and have warned customers against doing business with the accused owners, and have utilized aggressive physical and emotional tactics to gain an upper hand during investigations or in court” (as summarized by Ma 2012, p. 702). Using public records, the Center for Food Safety found that “As of November 28, 2012, Monsanto had filed 142 lawsuits against farmers.” In addition, the Center for Food Safety estimated that Monsanto has pursued between 2,391 and 4,531 patent violation cases against farmers, collecting pretrial settlements between \$85 and \$160 million (Kimbrell and Mendelson 2012). However, these estimates are allegedly based on regional fact sheets that were removed from a Monsanto website sometime in 2006–2007.

Philosophically speaking, many of these concerns about patent infringement might be usefully analyzed in terms of trust and trustworthiness. Monsanto claims that it will never bring suit for patent infringement in accidental contamination cases. However, based on claims that Monsanto uses heavy-handed tactics in deliberate infringement cases, some farmers and other critics believe that Monsanto’s primary motive is its own bottom line, and so it does not have the good will toward farmers that trust requires (compare Baier 1986; see also Scheman et al. 2011; Scheman 2011).

Research Restrictions

Some groups of scientists have expressed concerns about the use of intellectual property rights to restrict independent research. In February 2009, a group of 24 entomologists submitted a short public comment to the EPA’s Federal Insecticide, Fungicide, and Rodenticide Act Scientific Advisory Panel (FIFRA SAP) (an external oversight and advisory body that covers, among other things, the agency’s pesticide program, which regulates certain GM crops) (Shields 2009). The scientists argued that the license agreements required to purchase patented GM seeds prohibited independent research, with two harmful effects. First, they “inhibit public scientists from pursuing their mandated role on behalf of the public good unless the research is approved by industry”, that is, scientists could only develop the technology further – say, developing varieties that were well suited to the growing conditions of a certain place – with the rightsholder’s permission. Second, “no truly independent research can be legally conducted on many critical questions regarding the technology, its performance, its management implications, IRM [insect resistance management], and its interactions with insect biology.” In other words, there was no (legal) independent research on the effects of GM crops on nontarget insects such as butterflies or the evolution of pesticide resistance. Just over a year later, a longer discussion of these issues was published as a commentary in the journal *GM Crops* (Sappington et al. 2010).

In response to these concerns, the American Seed Trade Association [ASTA] “negotiated an agreement between university scientists and seed companies to protect industry property rights while enabling university scientists to conduct research with more independence” (Glenna et al. 2015, p. 151; see also Sappington et al. 2010, p. 2). A recent survey of entomologists found that 63 % of all respondents ($N = 38$) were either satisfied or very satisfied with the ASTA agreement; however, among public-sector researchers ($N = 29$), 31 % agreed that their “research on the efficacy or environmental impact of a genetically engineered crop had ... been hindered by an industry partner,” and 59 % agreed that “[i]f there were no bag-tag restrictions on university research, [they] would ... conduct research on the efficacy or environmental impact of a genetically engineered crop” (Glenna et al. 2015, Tables 1 and 2, pp. 160–161). The team that conducted this survey interpreted these results as evidence that “these entomologists think that the ASTA agreement is better than the previous arrangements, even though many still believe that the intellectual property protections create obstacles for research” (pp. 161, 166). In a free-response section of the survey, respondents raised concerns that industry partners can restrict access to junior researchers or scientists whose findings they do not like (pp. 163–164) and create bureaucratic delays that discourage research and publishing findings (p. 162). All together, the team concluded that “intellectual property protections in GE crops are hindering some types of agricultural and environmental research” (p. 166).

The philosopher of science Justin Biddle has also raised several concerns about the ASTA agreement (Biddle 2014, p. 19). First, the agreement covers only scientists at about 100 US research universities and no scientists outside of the United States. In addition, the agreement does not include certain areas of research. Research for “detecting the presence or absence of patent-protected traits” is explicitly not included, and it is not clear whether research on health effects is included. Further, the agreement is voluntary and “the seed company ... can revise or completely

abandon the agreement at any time.” And finally, agreements or academic licenses are developed on a company-by-company basis, although the American Seed Trade Association has developed a set of “principles and objectives” for these agreements (“Research with Commercially Available Seed Products” 2009).

Feeding the World

One of the most popular arguments for the development and use of GM crops is their value for “feeding the world”, that is, for improving food security, especially given a growing world population and the potential effects of climate change. For example, a “communicator’s guide” prepared by an agricultural biotechnology industry organization identifies feeding the world as one of its four “key messages” (*Food Biotechnology: A Communicator’s Guide to Improving Understanding* 2013).

The impacts of GM crops on yields have been heavily studied by both agronomists and agricultural economists for about 20 years. Until recently, the only summaries of this body of research were review reports, which generally did not include detailed discussions of their literature search and statistical methods. One such review report is Doug Gurian-Sherman’s “Failure to Yield” (Gurian-Sherman 2009), produced and released under the auspices of the Union of Concerned Scientists. Gurian-Sherman holds a PhD in plant pathology from the University of California [UC] Berkeley. This report continues to be widely cited by GM critics both online and – to a lesser extent – in some scholarly writing. Gurian-Sherman estimated that HT maize had not seen increased yields and that Bt maize had seen increased yields between 7 % and 12 % but only when insect pests are present (Gurian-Sherman 2009, pp. 2–3).

Another widely cited review report was prepared by Janet Carpenter, an agricultural economist (Carpenter 2010). This report was supported by CropLife International, an agricultural biotechnology industry organization. Carpenter estimated that GM crops are 0–7 % more productive

in developed countries and 16–85 % in developing countries (Carpenter 2010, Table 2).

Neither Gurian-Sherman nor Carpenter explained their methods in detail. At best, their findings depend heavily on their ability, as experts, to perceive the essence or truth underlying the data (Daston and Galison 2007, Chap. 2). At worst, they're selecting the findings that best support the political and economic interests of their sponsors. Elsewhere, one of us argues that the disagreement between Gurian-Sherman and Carpenter extends to deep views about the aims of scientific research: Gurian-Sherman cited carefully controlled experimental studies, with the potential to prove causal relationships, while Carpenter cited surveys of farmers that would provide a better basis for extrapolation (Hicks 2015).

In the last few years, groups of agricultural economists have undertaken meta-analyses of the primary research on GM crop yields. Meta-analyses are similar to review reports, in that they summarize the findings of a large body of primary research. But meta-analyses generally involve a systematic search of the literature and more sophisticated statistical techniques, and these methods are usually described in some detail when the meta-analysis is published. Whereas review reports depend on expert perception, meta-analysis presents itself as approximating an ideal of mechanical objectivity (Daston and Galison 2007, Chap. 3).

As far as the authors of this entry are aware, the first meta-analysis of GM crop yields was prepared by Finger et al. (2011). They focused on maize (corn) and cotton, primarily Bt varieties; much of their data come from India, China, Spain, South Africa, the United States, and Argentina. They found that Bt cotton had a statistically significant greater yield in India than conventional cotton; the difference was not statistically significant for the other countries. They did not find a statistically significant difference in yields for maize in any country.

The Finger et al. meta-analysis has not been highly cited. A more high-profile study was published in 2014 in *PLoS ONE* by Klümper and Qaim (2014). Klümper and Qaim examined data for Bt and HT varieties of maize, cotton, and

soybeans. They found that IR crops were associated with 25 % greater yields, while HT crops were associated with 9 % greater yields.

Both of these meta-analyses provide details about their literature search and construct statistical models to control for other factors that influence yields. However, the epistemic quality of a meta-analysis is limited by the epistemic quality of the primary research that it summarizes. And there are some notable limitations in the primary research on GM crop yields.

First, some of this primary research does not include measures of variance, and sometimes even sample sizes are not reported. In other areas, such as biomedical research, these statistics are considered necessary for including a piece of primary research in a meta-analysis. Klümper and Qaim acknowledged this limitation (p. 5), but it's unclear whether it's a small problem (with just a small number of studies) or a large one (affecting many studies). In personal communication, Matin Qaim declined to clarify the magnitude of the problem.

Second, much of the data (206 out of 451 findings or nearly 46 %) come from studies conducted in developing countries concerning Bt cotton. By contrast, this research includes very little data on soybeans in developing countries (nine findings), and there does not appear to be any data for stacked maize as such. And yet the majority of maize grown in the United States is stacked, and effectively all of the soybean crop in Argentina is Bt. [James (2012), p. 47, estimates 20.2 MHa of GM soybeans in Argentina in 2012; Markley (2012), p. 2, estimates 18.8 MHa of total soybean cultivation. MHa is millions of hectares; 1 MHa is 10,000 km² or about 3,900 mile². Twenty million hectares is about half of the total area of Germany.] This raises both statistical and epistemic concerns. Statistically speaking, the overall means reported above are based on biased samples: they oversample cotton in developing countries, undersample soybeans in developing countries, and do not include stacked maize at all. Without statistically correcting for this bias, the overall means may not be reliable. Klümper and Qaim did construct a model that corrects for this bias, but the results highlighted in their abstract – and

reported above – are based on an uncorrected mean. In addition, it is unclear whether these data give us a good basis for extrapolation. We have a large amount of evidence concerning the productivity of Bt cotton in developing countries, and some evidence concerning HT soybeans in developed countries (65 findings), and a very small amount of evidence for HT maize (2 findings) and soybeans in developing countries. What do these data tell us about HT soybeans in Argentina? Can the data for Bt and HT maize to make predictions about stacked maize somehow be combined? Philosophers of science have raised concerns about extrapolation and meta-analysis in other contexts (Stegenga 2011; Douglas 2012); they seem to be of particular relevance here.

Summary

While the controversy around genetically modified organisms often focuses on human health concerns, there are also a variety of environmental, political, legal, and social issues at play. Major environmental issues include the evolution of pesticide-tolerant organisms, gene transmission, the impact of GM crops on pesticide use, and direct and indirect effects on other species. Political and legal concerns often involve the power that intellectual property rightsholders have to restrict the activities of farmers and researchers. Finally, there are significant scientific controversies over the value of GM crops for addressing food security.

Green Restaurants

Introduction

At first sight, the issue of “green restaurants” would seem to be of little relevance to those concerned with the major problems of food and agricultural ethics – problems that concern, for example, food justice and the sustainable use of the world’s resources. However, the realization that global food production is now one of the

leading causes of greenhouse gas emissions and that, in the USA at least, almost half of an individual's annual spending on food consumption is devoted to eating outside the home in the restaurant and suchlike places suggests that "green restaurants" offer an increasingly valuable approach to environmental stewardship in North America and the UK – the main focus of this entry – where the environmental and health problems of the so-called Western diet are most acute.

Certainly, concerns about the part played by fast-food restaurants in the creation of so-called food swamps (areas with many low-cost chain restaurants but with little access to more healthy food) have highlighted the importance of access to affordable "greener" food choices if the projected increases in North American obesity and diabetes rates are to be avoided (Polsky et al. 2016). Restaurants in this continent have also recently become a focus among researchers of food waste and food justice, since restaurants in particular have been identified as one of the leading sources of food thrown away on a daily basis (Stuart 2009). The opportunity thus exists both to reduce emissions and to feed more people if such waste can be reduced or better managed in some way – and, in meeting this challenge, lies one of the many environmental benefits of "green restaurants."

The term "green restaurant" may be defined as a general concept that includes a broad variety of restaurants and catering establishments which, for a number of reasons, all share a common goal – that of respecting the environment in some way or another.

The reasons for such respect can be quite different. Thus, some restaurants are vegetarian on primarily religious grounds because either their owners or the customers they serve are from faiths that teach the avoidance of eating meat (examples include Hindus, Jains, Buddhists, and Seventh-Day Adventists). Other restaurants may practice vegetarianism on more general ethical grounds (to avoid, e.g., the cruelty to animals that modern factory farming has often caused) or because of food safety concerns (such as the increasing cases of *E. coli* in the commercial food chain) or because of a concern to limit the more general effects of meat eating on global warming.

Similarly, respect for the environment can be shown in a variety of ways and is by no means limited to vegetarian restaurants. Thus, restaurants that place an emphasis on serving organic, locally sourced, sustainable food may also be considered "green restaurants" to the extent that those practices themselves promote a healthy environment and a healthy cuisine (through, e.g., the elimination of pesticides or GMOs in the food served).

Having now defined the broad concept of "green restaurants" and indicated their general relevance, this encyclopedia entry will first consider the importance of their historical background. Drawing on their origins in early nineteenth-century vegetarianism, it will be shown that today's "green restaurants" continue a "countercultural" critique of the effects of modernization upon more traditional practices of farming and food production. The second part of this discussion turns its attention to the present role of "green restaurants," especially in North America and the UK, and considers the development of certification procedures that now allow consumers better ways to evaluate competing restaurants' claims to respect various levels of "greenness." A third and concluding section offers an assessment of the current values and challenges that face "green restaurants" – issues that include the need for this sector of the restaurant industry to increase in size and to avoid accusations of "greenwashing" (in which an apparent concern for the environment is used for primarily economic gain and the term "green" is thus co-opted by business as simply another marketing tool).

Historical Background

According to Spang (2000), the origins of the modern Western restaurant lie in Paris in the 1760s, and from its beginning was an institution as much concerned with human health as with serving food. The origin of the word "restaurant" itself comes from the "restoratives" (literally, "restaurants") that were sold as soups to an aristocratic clientele in need of rejuvenation. These early

restaurants were not the first places to provide opportunities to eat outside the home (since taverns and hostelrys had long existed) but they were, in Spang's view, the first to commodify cuisine and commensality through the use of menus and fixed prices. Popular as a new type of public space, within only a few generations the idea of the restaurant spread across Europe and North America and soon became identified as an opportunity for early vegetarian movements in Britain and the USA.

Among the earliest public demonstrations of what might now be called a "green diet" was at the "Concordium," a cooperative and utopian community founded southwest of London in 1838, where visitors could tour a garden planted to promote self-sufficiency and taste Graham bread made with raisins baked on the premises. Promoting temperance as well as vegetarianism, such groups often found restaurants preferable to coffee houses since by eating in public, they could "encourage the spread of their dietetic principles and offer a resort for their converts" (Gregory 2007: 134). The earliest known vegetarian restaurant in the country, "Barnesley's Vegetarian and Temperance Hotel" in Manchester, dates from the 1850s – the same date that William Sylvester Graham and the American Vegetarian Society were pioneering vegetarian restaurants in Boston, Chicago, and New York, to promote an ascetic and healthy individual lifestyle. Part of a critique of the growing industrialization and urbanization of society, it is not surprising that vegetarian restaurants found focus in metropolitan centers. By 1889, for example, it is estimated that London contained 34 of the 52 vegetarian restaurants recorded in England – restaurants that were frequented by people as various as the playwright George Bernard Shaw, the young Mahatma Gandhi, and even, on one occasion, by the fictional detective Sherlock Holmes (Preece 2008: 309–319).

If early vegetarian movements provided the foundation for what we would now call "green restaurants" in nineteenth-century European and North American cities, subsequent waves of immigration to those centers from many parts of the world brought with them many groups whose

cultures and religions taught them to avoid eating meat and thus have led to an increased demand for cuisines that are vegetarian in focus. Examples range from the many East Indian curry houses found in London's Brick Lane to the small Doukhobor restaurants of British Columbia's interior that serve a cuisine derived from their Russian homeland. Indeed, as part of the rise in "ethnic restaurants" that typified many large centers since the 1950s (Nash 2009), this increase lasted well into the 1990s, by which time the "environmental" movement was beginning to indicate how unsustainable meat eating was, and a series of "food scares" (especially the UK's "mad cow" or BSE epidemic) had illustrated the importance of food security for restaurant customers (Paarlberg 2010).

A key moment in these latter developments came with the publication of the United Nations' Food and Agriculture Organization's 2009 report *Livestock's Long Shadow* which argued that the world livestock sector was "responsible for 18 % of greenhouse gas emissions measured in CO₂ equivalent," an amount it concluded is "higher than transport" (Steinfeld et al. 2006: xxi). Such estimates have proved controversial, especially with the livestock production industry, but they have prompted a number of writers to suggest how deleterious meat eating can be for the environment and to promote more healthy alternatives. As popular author and food activist, Anna Lappé, has written, when "[c]hallenged to name the human factors that promote climate change we typically picture industrial smokestacks or oil-thirsty planes and automobiles, not Pop-tarts or pork chops. . . . [So] move over Hummer. Say hello to the hamburger" (2010: xv).

Faced with such findings, a number of environmental scholars and food activists now promote the benefits of diets much less dependent on meat than is currently the case in many Western countries, where a rise in affluence has brought with it increasing levels of meat eating and obesity (Smil 2002). Suggested options have ranged from the complete abandonment of meat (which would free up enough cereals and legumes to feed an additional 3 billion people) to its avoidance on 1 day a week – the so-called Meatless Monday

movement promoted by the Johns Hopkins University's Bloomberg School of Public Health – which, while not enough on its own to avoid a likely increase of 2 °C in average world temperatures, would still be the equivalent of taking 273 million cars off the road, based on typical US passenger vehicle emissions, and would achieve the same reduction in emissions as switching to entirely local diet (Kim and Santo 2015; Paarlberg 2010; Smil 2002: 619–620).

Today's "Green Restaurants": The Development of Certification

With restaurants such a part of modern life, especially in North America – where it is now estimated that the average individual now spends 44 % of their annual food budget on food consumed away from home (Green Restaurant Association 2016) – it is hardly surprising that these trends have translated into a much more environmentally aware customer and one that is increasingly looking for ways to support sustainability and health through their choice of restaurant dining.

Faced with the desire to support "green" initiatives, today's consumers have a number of options available. Thus, they can support the many already existing vegetarian restaurants to be found in their community. As has been shown above, these establishments have historically provided an important alternative for those who wish to avoid the many problems of the "Western diet." Indeed, the growing popularity of this option has led to a rapid rise in the number of new vegetarian and vegan restaurants in many North American cities – to take Montreal as but one example, a total of three new vegetarian restaurants have opened since 2010 within a 5-min walking radius of one of the city's universities – and illustrates also the importance of younger demographic groups in this search for an alternative. Other options include the avoidance of specific foods that are derived from endangered species or unsustainable fishing practices or to support the growing number of "green restaurants" that (as this entry will next discuss in more detail) have developed in the last 30 years offering either

an "informal" or "certified" assurance of their commitment to the environment.

The informal option has its beginnings with individual restaurants that have sought to market themselves as "green" in terms of their own experience or decisions to adopt more environmentally friendly menus. Illustrative if contrasting examples include a well-known restaurant in downtown Durham, New Hampshire, and an upscale one located in Bristol's Bordeaux Quay in England. Thus, in a series of informative panels to be found on the walls of its dining room, the former endeavors tell the story of their family's 20-year commitment to the environment, the steps they take to assure sustainability, and the lengths to which they have gone to source locally: as a note on their 2016 website shows, "If you've eaten [here] this summer, you've likely eaten produce directly from [our] own garden." The latter, a much more expensive restaurant, has sought since its foundation in 2006 in an old dockside building to become as sustainable as possible. In its early years, it achieved this ambition by adopting its own environmental goals (concerning, e.g., levels of local sourcing, composting, and recycling; reduced energy and water consumption; and the use of sustainable materials in its renovation). In more recent years, it has reinforced its mission with the adoption of formal certification as a "Sustainability Champion" from the UK's Sustainable Restaurant Association (an organization discussed in more detail below). This trend toward a more formal certification has become increasingly popular in the UK and the USA since it provides consumers with some type of guarantee that foods served meet objectively based standards of "greenness" and gives a wider credibility to restaurants that make such claims.

In the USA, the growing importance of "certified" "green restaurants" was recognized as early as 1990 with the establishment of the Green Restaurant Association (GRA) in San Diego, a nationwide body that aims to promote green dining and to provide certification for those restaurants that meet its requirements. Being a group aimed mainly at the food industry, the GRA's aims are primarily economic, but it is interesting to see how the environmental goal of "greenness" has

proved to be so important to consumers that it has itself become a marketable commodity – one sometimes labeled as “greenwashing” – and openly acknowledged by the GRA as one of the reasons to seek accreditation. Thus, to quote their website, “[w]hether your goal is to decrease costs, become zero waste, or simply make a few changes that customers will see,” once a restaurant seeks green certification from the GRA, “a consultant will provide detailed solutions to help you reach your goal” (The Green Restaurant Association 2016).

The GRA’s certification criteria, “Green Restaurant 4.0 Standards,” make interesting reading not only because their level of detail shows the care the GRA takes over accreditation and the need for a consultant’s help but also – by itemizing all the possible steps a restaurant could be taking to help the environment – provides a useful general inventory of the major issues that any restaurant or customer needs to consider in their path to “greenness.” Thus, according to the GRA’s current scheme (as detailed more fully on their website), points are awarded across the following major categories of environmental concern: energy and water efficiency, waste management, recycling of dishes and utensils, the use of sustainable furnishings, the reduction of chemical pollutants, and the promotion of “sustainable food” (defined as vegan or vegetarian, “organic,” or “local”). Restaurants that pass the threshold level for certification are placed into either one-, two-, or three-star categories of “green restaurant,” depending on the total number of points earned.

Examples of restaurants that have been certified in this way range from the first certified organic restaurant in New York State to a Peruvian-Italian restaurant in Boston’s North End that since going green in 2000 has managed to recycle or compost almost all its waste and currently saves \$1,300 a year by switching from paper towels to energy-efficient hand dryers in its washrooms.

By late 2015, according to its website, a total of 443 restaurants in the USA and 5 in Canada met the GRA’s criteria. This total is perhaps indicative of the rapid growth of the phenomenon in recent

years since it is a number that has risen by over 50 percent since 2011 when there were 292 listed on the GRA site. Of course, such an increase must be set into its wider context, and it is therefore important to recognize that such numbers are still only a very small fraction of the over 945,000 “full-service restaurants” the GRA estimates to be operating in the USA (a total that is predominantly “nongreen”).

Small as they are in absolute terms, further examination of the GRA data on certified green restaurants in 2015 is useful since it indicates the main features of their geographical pattern across the USA. Thus, of the 443 green restaurants found across the country, almost half (218 or 49 %) are located in the six metropolitan areas of Boston (56), Washington, DC (29), Chicago (23), Los Angeles (18), New York (69), and San Diego (23). Clearly, such types of green restaurants in the USA are predominantly an urban (and principally a metropolitan) phenomenon. Given such data, it is no surprise to find that while half of the total number of restaurants (223) listed in 2015 are found in the four states of New York (83 restaurants), Massachusetts (60), California (56), and Illinois (24), over half of the total number of states (25 out of the 41 states listed) have fewer than 5 restaurants each – a factor attributable to their relatively low population densities and low rates of urbanization. There are, for example, only two certified green restaurants in the whole of Wyoming and one in North Dakota.

Distribution by category (the number of stars awarded in the Green Restaurant Association’s system) does little to alter these basic urban-rural polarities. Thus, with the highest proportion (20 %) of the national total of 195 certified restaurants found in the three- and four-star categories, and with well over half (or 40) of its certified green restaurants falling into one of these two categories, New York State could perhaps be considered the “greenest” part of the USA. Overall, when their totals are combined, the four states of New York, California, Illinois, and Massachusetts represent 49.7 % of the highest ranked green restaurants in the country in 2015.

The GRA is by no means the only organization in the USA promoting restaurant sustainability, a

fact that itself indicates the growing importance of “greenness” to food consumers. Indeed, the largest restaurant organization in the country, the National Restaurant Association (NRA) with over 500,000 members, has been explicit that an important reason for the recent launch of its “Conserve Program” is that “Serving Up Sustainability” (to use the program’s motto) has become one of the latest consumer trends across American restaurants (NRA 2016). Rather than provide a strict certification scheme, however, this program seeks to encourage NRA restaurants to become more sustainable through a process of self-assessment and guidance. Developed in this way, the particular restaurant’s own route to sustainability thus becomes an “organic, honest sustainability story” that the NRA’s Conserve Program suggests can be shared with local networks of customers and friends. Many restaurants – not all of them affiliated with the NRA – have chosen to adopt such an approach, one that relies much more on “word of mouth” and personal testimony to attest to the genuineness of their “green restaurant” claims than it does on more formal membership of an organization.

In the UK, there are two principal organizations that offer certification for restaurants that aspire to be “green.” The oldest is the Soil Association, founded in 1947 and now the UK’s leading environmental charitable group promoting sustainability, organic farming, and human health. According to its website, its organic certification program is responsible for certifying over 70 % of all organic products sold in the country and, as part of that program, has in the last 5 years added a “Food for Life Catering Mark” as an endorsement for caterers (Soil Association 2016). Aimed mainly at institutions (such as hospitals and educational establishments), the Soil Association’s award of its “Catering Mark” recognizes those caterers that have committed themselves to providing food that is not only freshly prepared but also free from undesirable additives and genetically modified organisms, meets national nutritional standards, and is obtained with respect for animal welfare. Depending on the total number of points

awarded for these categories, there are three levels of award. To attain the highest (the “gold” rating), awardees must ensure they obtain their supplies from ethical and environmentally friendly food producers. It is worth noting that by awarding points for the number of nonmeat days in their catering schedules or the proportion of nonmeat dishes in their menus, the Soil Association is clearly recognizing the links between what is eaten (especially meat) and levels of greenhouse gas emission.

The Sustainable Restaurant Association (SRA) is Britain’s more recent but larger “green restaurant” organization. With over 5,500 member restaurants, the SRA aims to recognize and promote sustainability by measuring achievement across three major components (food sourcing, social concerns, and environmental responsibility) – components that are themselves broken down into 14 separate factors, such as “sourcing from farmers committed to higher levels of environmental stewardship” (The Sustainable Restaurant Association 2016). While the SRA’s focus is on an overall “holistic sustainability,” it does recognize levels of achievement toward that goal and currently lists 94 restaurants in its highest three-star rating. As noted with the GRA, the geographical pattern of these restaurants shows a predominantly metropolitan focus – although the “Most Sustainable Restaurant of 2015” was to be found in Caithness, Scotland.

Conclusions

Food scholars have suggested that new food fashions are forged in the public arena and not in the home because that is where such habits are first seen and then widely diffused. If this is the case, then “green restaurants” have an important role to play in the promotion of new “sustainable” food habits that can reform both public and private patterns of consumption, especially in more affluent parts of the world where the health and environmental effects of the “Western diet” are especially challenging.

This was certainly the vision of the early vegetarian movements who used restaurants as an

integral part of their mission, and it has become a justification for modern “green restaurant” associations as they respond to the call of environmentalists and those concerned with food safety with certification programs that seek to promote sustainability, and with individual stories of success that position restaurants as environmental leaders in their own communities.

Of course, a great deal remains to be done. Certified “green restaurants” currently account for only a fraction of the public eating establishments that exist. Given the cost, and the often lengthy procedures required to become certified, this is not surprising but it is indicative of a fear that “greener” practices are more expensive, at least in economic terms – a belief still prevalent despite the associations’ own examples of cost savings. The appeal to economics can itself become a two-edged sword and has led some consumers to see “green restaurant” certification as simply another example of the “greenwashing” of business rather than any real commitment to sustainable practice.

From the wider perspective of environmental stewardship, the number of certified “green restaurants” is far less important than the need for restaurants as a whole to become more sustainable. In this respect, the often “informal” steps taken in small family-run restaurants to adopt more environmentally conscious menus will be as valuable as those “green practices” heralded by the major cafés and fast-food chains. As the “Meatless Monday” movement has argued, the combined effects of individual decisions about eating behavior could make substantial inroads into projected levels of global warming. “Green restaurants” are an essential part of this process, but in the final analysis, of course, it will be up to the consumer to insist on change. In the words of the Slow Food Movement, “Let’s not eat up our planet. Fight Climate Change.”

Green Revolution

[Agricultural development](#); [International development](#); [Modernization](#)

Introduction

The period after the Second World War witnessed major changes in the primarily agrarian peasant economies of Asia. Fueled in part by new agricultural technologies, systems of state support, and strategic alignments with capitalist or communist nations, governments in unaligned nations undertook massive projects in internationally supported agricultural development collectively referred to as the green revolution. This complicated process fundamentally changed agrarian economies by: (1) introducing input- and capital-intensive farming methods; (2) replacing agricultural labor with technology, thus moving people out of agricultural sectors while simultaneously creating markets in the industrial economy; (3) institutionalizing various elements of the development apparatus through international aid, research collaborations, and trade; and (4) expanding the role of the state in everyday life. This move was perhaps strongest in India, where the state collaborated with both Soviet and American organizations to bring agricultural infrastructure and high-yielding varieties of wheat and rice to farmers. As a result, gross production of commodity grains rose in tandem with increases in state-funded agricultural infrastructure, industrially produced agricultural inputs, interactions between peasant farmers and state bodies, and the urban population. This article discusses: the early technological and institutional history of the green revolution, the cold war geopolitics of green revolution development, state and peasant responses in South

Asia, and the lasting impact of the green revolution on international development.

High-Yielding Varieties and Other Green Revolution Technology

This section discusses the historical, institutional, and technological context of green revolution agriculture. By the 1930s, American and European agriculture was incorporating a suite of new technologies and inputs made possible by scientific discoveries in chemistry, genetics, and engineering, along with public and private institutions capable of bringing them to farmers. Where most farmers globally continued to produce their own agricultural inputs, manage a subsistence and market economy, and controlled agricultural labor and knowledge to an extent, the changes in Euro-American farming systems allowed for a new externalized and commodified form of agriculture. Following the industrial trends seen in factories, farmers began to resemble workers who purchased tools and produced commodities in an attempt to achieve agricultural efficiency. This synergy benefitted industry, states, and commodity markets, although its effects on farmers were more mixed.

At the heart of this new relationship to agriculture was the hybrid seed (Kloppenborg 2004). Designed using the newest understandings of Mendelian and Darwinian genetics, seed breeders developed hybrid seeds through cross pollination, allowing breeders to select for particular traits, and later backcrossing, in which parent lines are bred with descendent lines to increase the uniform performance of those traits. When farmers purposively saved such hybrid seeds from their fields, the following harvest often suffered losses in yields and increased disease susceptibility because of inbreeding. Thus, the hybrid seed came to resemble a commodity. Rather than use open pollinated varieties that could be saved and gradually improved or save hybrid seeds that would produce inferior products in subsequent years, farmers began to adopt hybrid seeds that were purchased new each year.

Increases in yield were achieved in three ways. First, breeders identified naturally occurring resistance to plant pathogens and bred those traits into plant lines. This required no new technological changes in plant breeding but was built on the early twentieth century rediscovery of Mendelian genetics. This agriculturally beneficial response was termed “hybrid vigor” or “heterosis.” Second, breeders recognized new industrial processes by which nitrogen could be industrially fixed from the air. Many plants used nitrogen fertilizer to grow taller and thus became susceptible to lodging and other weather damage. By breeding dwarf varieties with hybrid lines, plant breeders created crops that could use an excess of fertilizer to grow larger and heavier grains. Because chemical fertilizers decreased soil moisture content and increased crop water demands, farmers began to rely more heavily on irrigation and infrastructure provided by states and private builders. Finally, disease-resistant plants were used in conjunction with newly available chemical pesticides, allowing farmers to plant hybrid crops bred to overproduce when given extra nitrogen in monocultures with less fear of pest predation. Because of their increased production, given the right combination of nitrogen, water, monoculture farming, and pesticides, such seeds came to be called high-yielding varieties or HYVs.

Plant breeder and pathologist Norman Borlaug is perhaps the most influential individual of the green revolution. Trained as a plant pathologist, Borlaug worked with the DuPont Company before representatives from the Rockefeller Foundation and US government asked him to lead an agricultural modernization project in Mexico (Hesser 2006). In an analogous push to that seen in agrarian economies in Europe and the USA through the 1920s and 1930s, the Mexican government of the 1940s sought to increase commodity production, replace farmer knowledge and labor with off-farm inputs, and move rural populations into urban and industrial sectors. Under the mantle of development or agricultural modernization, this pattern, which further integrated rural farmers into industrial capitalism, would be repeated throughout Latin America, Africa, and Asia.

Borlaug worked with the Mexican government to breed wheat that would flourish in the new agricultural normal: monoculture, dense planting, fertilizer intensive, machine-harvestable, and water intensive. Taking advantage of longer tropical-growing seasons that allowed him to breed two generations of wheat in a variety of climactic conditions in northern and southern Mexico, a faster breeding method termed shuttle breeding, Borlaug identified wheat varieties that would produce large seed heads, would produce under a variety of light and temperature conditions, and could survive in close proximity without succumbing to disease or rust fungus. However, Borlaug’s hybrids suffered from lodging, in which they would become top-heavy and fall over during strong winds or rains. To solve this problem, Borlaug crossbred his varieties with dwarf wheat strains originally developed in Japan, particularly a cultivar known as semi-dwarf Norin 10. The resulting hybrid wheat strain used nitrogen fertilizer to create a larger seed head rather than a taller stem, thus preventing lodging. When incorporated into the system of fertilizers, pesticides, irrigation, monoculture, and machinery, Borlaug’s wheat seeds became the first HYVs.

The 1950s witnessed an explosion of state infrastructure, private sector growth in factories repurposed to build tractors and construct fertilizers rather than tanks and bombs, and increasingly interconnected global trade networks. By increasing plant yields and reorganizing agriculture to fit within industrial capitalist conditions, Borlaug was catapulted to international fame and new responsibility. Under the mantle of international development, Borlaug worked with national governments, philanthropic organizations particularly including the Rockefeller and Ford foundations, and arms of the United Nations to spread HYVs, along with the state infrastructure and agribusiness that accompanied them, to the Middle East and South Asia. His shuttle-breeding approach would later be repeated with dwarf rice varieties in the Philippines, and Borlaug received the 1970 Nobel Peace Prize in recognition of his contribution to increased food production.

Just as important as Borlaug's scientific efforts was the creation of an international network of scientific experts who could share technology and plant resources across scientific institutions. Previously, this role had been filled by state agencies, particularly the American navy and its imperative to send potentially lucrative germplasm back to American scientists, and philanthropic organizations with vast international networks, such as the Ford and Rockefeller foundations. Founded in 1971, the Consultative Group for International Agricultural Research (CGIAR) system established 15 institutions in 14 countries with specific crop foci and a mission to improve food security and yields. CGIAR centers, which linked the Philippines' International Rice Research (IRRI) Center and Mexico's International Maize and Wheat Improvement Center (CIMMYT) where Borlaug first developed HYVs, allowed green revolution scientists to share germplasm and train new agricultural experts in developing countries. The CGIAR system initially received major funding and support through the American philanthropic Ford and Rockefeller institutes in coordination with the World Bank. These organizations worked with states to oversee agricultural research and development, helping to design national agricultural policies, promoting input-intensive farming models, and aligning national production with the goal of exporting cash-crops to international commodity markets. IRRI in particular worked to distribute both the package of HYV technology and the American-style consumer capitalist mindset that accompanied it through public education programs and the institution's high modernist design. Although their influence in international development has diminished as private agribusiness and new philanthropic groups have assumed a growing importance compared to the state since the neoliberalist policies beginning in the 1980s, CGIAR centers were crucial to the initial spread of green revolution technology and agricultural logic (Kloppenborg 2004).

Counterfactual models show that the green revolution led to increased yields in the developing world (Evenson and Gollin 2003), but it is difficult to attribute yield or income gains to any

individual element of the green revolution package. The added cost of the total green revolution package, including seeds, fertilizers, mechanization, pesticides, and interest rates, led farmers to earn less per unit with green revolution crops while the crops themselves underperformed when not provided with the optimal combination of irrigation and fertilizer. Overall, the green revolution allowed farmers to put more calories into the global market at a lower price, but this success is tempered by changes in agriculture as a mode of production (Cullather 2013). The push for monoculture and industrial inputs in agriculture throughout the developing world replaced and actively sought to displace biodiverse subsistence farming with cereal export agriculture integrated with industrial inputs produced in urban centers by displaced labor.

Second, the green revolution's impacts were not evenly distributed across all farmers. Like other models of technological change, green revolution innovation often began with particularly well-connected, affluent, engaged, or interested farmers (Griffin 1974; Gupta 1998; Shiva 1993). In some instances, this meant that the benefits of new farm inputs went mostly to those farmers who could afford them or who had special relationships with agricultural officers. In other situations, the farmers who provided early success narratives for the green revolution added extra labor or capital investments, in effect trying harder, with the new varieties. Effectively, much of the green revolution benefits went to those farmers who one would expect to do best regardless, while farmers with poor access to resources were forced out of agriculture. The land tenure reforms that accompanied agricultural changes also reformed social life by reorganizing rural means of production. In Bali, new methods of rice management disrupted efficient systems overseen by water temple priests and led to immense increases in chemical use (Lansing 2006). In the Philippines, green revolution policies turned the Philippines into an exporting, cash crop economy. Ironically, Filipinos moved abroad or into other sectors and the Philippines on grain from Thailand, Japan, and China. Similarly, Guatemalan Maya farmers lost land to larger farmers backed by the state, who

used the newly landless peasantry as a reserve labor force for coffee, banana, and cattle (Ross 1998).

Third, the HYVs planted during the green revolution were destined for international markets rather than local consumption, meaning that the food security benefits of the green revolution came more from increased incomes rather than from increased food production. In fact, several countries became net importers of food products as a result of large-scale HYV planting. India, the Philippines, and Mexico, all home to international crop breeding centers and all major agricultural producers, became net importers of wheat or rice because the state moved rural producers to urban centers and used cheap international food aid programs to supply urban workers (Cullather 2013; Griffin 1974). Green revolution farms often produced greater harvests, but only of some crops, only under certain conditions, and only to the benefit of some farmers.

Cold War Geopolitics and the Green Revolution

This section discusses the ways in which the green revolution fit goals of international development and global geopolitics between 1950 and 1970. Because of their close association with international development, the goals of the green revolution were never separate from Cold War geopolitics or the changing relationship between the peasant smallholder farmer and the state. Following a Malthusian logic, agricultural development in the 1950s–1970s assumed a mismatch between population and food resources (Perkins 1997; Ross 1998). America's philosophical and financial commitment to this ideology began with the postwar Truman administration, which saw agribusiness as a key front in the Cold War: win hearts and minds by winning stomachs. Green revolution developers saw postwar land grabs by peasants, especially Maoist insurgencies throughout Asia, as evidence that the Earth had run out of food or land to produce it. In combating imbalance with HYVs, state and private agricultural changes ultimately privileged landlords

producing grain for export and national imports of Western food commodities over seemingly inefficient smallholders. For the Rockefeller and Ford foundations, this push to modernize and capitalize agriculture in the form of larger export-oriented farms would serve also vested commercial interests in oil and agribusiness. Thus, the green revolution as forwarded by American philanthropic organization, the US government, and multinational corporations (MNCs) had a special interest in subordinating peasant agriculture, seen as backward, unproductive, and politically dangerous, to a commercial and capital-intensive international agribusiness. This, they hoped, would not only improve rural livelihoods and increase global grain production but also foster the spread of liberal, capitalist, Western democracy averse to communism or fascism.

The key, for both developing states and American foreign policy, was to change peasant mentalities and align rural people with the goals of the state. Food aid through the American Public Law 480 (PL-480) program made possible central planning goals to move rural labor into urban sectors by providing cheap grain and by pricing grain below the point at which farmers were willing to sell. Simultaneously, green revolution inputs, machinery, and public works projects like irrigation and electrification could be produced by new industrial labor and put to use by the largest farmers who were able to capitalize on the new combination of inputs and prices. American political scientists used the green revolution as a means to increase consumption and dissuade peasants from Maoism through consumer capitalism. Meanwhile, developing state governments used this new mode of production as a way to make their citizens more legible, connecting them to credit and infrastructure programs while increasing industrial production and thus growing GDP. For both interests, commodity producers connected to agribusiness would present less of a risk to state stability.

Given the Malthusian underpinnings of this Cold-War development, it is important to note the political economy of the relationship between rural hunger and green revolution. First, the wartime food crisis that led the Mexican state to

modernize wheat production stemmed in part from American purchasing shifts toward rubber and other nonfood crops, which peasants planted instead of maize. Neo-Malthusian theories about population/food imbalances gave plant breeders and developers a convenient frame for the necessity of their work. Furthermore, the massive shift in South Asian grain production was facilitated in large part by an overproduction of wheat in the United States. PL-480 food aid program sent high-yield grain to India, checking communist threats while relieving excess US grain stock. PL-480 provided the millions of cereal food grain tons needed to move rural labor to urban centers while lowering grain prices below a profitable margin for small farmers.

Borlaug's success in Mexico laid the foundation for a Cold War mentality that linked hunger and overpopulation to communism and national security. Hunger and population were thus serious national security threats linked to inefficient agriculture and rural political instability. Following this logic, Western states could save capitalism and democracy in the third world by providing superior plants and espousing the material benefits of consumer capitalism. Demographic surveys reinforced the image of the Asian countryside as primitive and crowded, especially in need of development. Ironically, anthropological case studies of the time showed that rural peasants were using their resources efficiently and desired better pay for their wages rather than increased yields (Cullather 2013). Yet in the aftermath of the green revolution, American and Asian leaders were able to celebrate the new seeds and the new state programs that enabled their harvest as state building tools. By supporting landlords, promoting agribusiness, moving rural labor to urban centers, and increasing the role of the state in peasant life, the green revolution sought to curb the spread of communism in Asia.

India: A Case Study in the Green Revolution

This section considers India as a case study for the local, geopolitical, and technological changes that

occurred during the green revolution. New wheat and rice varieties, their associated agricultural inputs, and the spread of agricultural experts would have profound impacts on how farmers organized village life. Additionally, India's political negotiations during the 1960s defined the "third world" as a balanced approach of developing states to Cold War geopolitics. Given national successes in raising grain production and bringing peasants into greater connectivity with the Indian state, India's experience with agricultural development would come to provide a model for development generally after 1970.

Following independence in 1947, the Indian state undertook a series of 5-year plans modeled after Soviet and American central planning initiatives (Guha 2008). In general, these plans sought to move peasant labor from rural agriculture to urban industrial sectors. This, the state hoped, would increase GDP, raise standards of living, increase exports, and bring citizens into more regular contact with the state. Agriculture was a necessary component of the industrial plan, which required rural labor and food to be produced for urban industrial centers. However, the state could not simultaneously seek to move farmers to cities as it raised agricultural production without international food aid to fill the production gap (Perkins 1997). Independent India at first relied on Pakistani wheat to feed urban citizens at low prices, but this proved to be both expensive and geopolitically embarrassing. Indian politicians furthermore recognized their large and impoverished peasant population as a potential threat to the stability of a modern, industrialized state. The United States began to have more direct interaction with India during the Kennedy administration, as the Cold War escalated. To gain the support of politicians sympathetic to socialism and suspicious of Western soft power, the American government, the Ford Foundation, and the Rockefeller Foundation offered aid through both PL-480 and international scientific cooperation. By the late 1960s, Indian politicians largely abandoned a model of small-scale village improvement in favor of agribusiness and increased cereal production through HYVs. In this way, they could meet basic urban needs while

industrializing the nation. Crop failure during the 1966–1967 harvest provided the perfect reason to introduce HYVs on a large scale.

When a successful 1968 harvest followed the 1967 famine in Bihar, the controversial and complicated set of policy changes came to be known as the green revolution, a triumph of science and planning over environmental limits. Technology intensified existing rural class tensions, profit margins shrank for 80 % of the farming population, and the state had few means to store grain long term (Cullather 2013). Still, overall production rose and urban populations, fed by green revolution crops, fueled the growth of an industrial sector. Indian and American officials declared that famine had been conquered, reducing the conflicts and contradictions of 20 years of agricultural development to a single event: the green revolution. Future food crises in Africa and Latin America would be solved using the green revolution model: a political package of seeds, pricing, financing, chemical inputs, and population management. Just as agriculture had conquered overpopulation and communism in India, so too would it be deployed under the guise of philanthropy and later neoliberal development to conquer poverty and terrorism in other postcolonial nations.

Conclusion

The green revolution relied on both technological and social changes to create a new mode of agricultural production. Technologically, the green revolution introduced an agricultural mode that followed industrial logic: expert knowledge and management through CGIAR centers and local extension; off-farm inputs produced on an industrial scale including pesticides, fertilizers, and machinery; an economy of scale that took the form of grain monocultures destined for export; a shift from household labor to capital and chemical inputs on the farm; and the use of the state as a mechanism for providing infrastructure and incentives for increased production. From the perspective of social organization, the green revolution effectively moved millions of peasant farmers out of rural economies and into urban or industrial

centers by providing new economic incentives and replacing rural labor with off-farm inputs. This both raised national gross domestic products and allowed states to have more direct influence in the lives of national citizens.

The agronomic consequences of the green revolution are more mixed. Wheat and rice yields rose in some parts of Asia but fell in others, while the HYVs themselves only overproduced for some farmers given the right combination of technology. Similarly, overall caloric intake increased in Asia as a whole, while biodiverse subsistence agriculture and local food security likely decreased as peasant subsistence agriculture turned into export-based cereal production. In Latin America and Asia, farmers planting HYVs have seen yields continue to rise but only in tandem with increased costs, especially those of pesticides and fertilizers. Increasing pesticide use encouraged an evolutionary treadmill in which pests adapt to new biocides and farmers buy even more powerful sprays. With the spread of chemical fertilizers and export-driven monoculture farming, some areas have seen depletions of trace minerals, increased erosion, and a decrease in soil moisture content. Both pesticides and fertilizers seeped into groundwater and river systems. Finally, the irrigation required for optimal performance of green revolution seeds led to soil salinization in some areas while the water diversions themselves heightened existing tensions between those with access to water and those without (Evenson and Gollin 2003; Griffin 1974; Gupta 1998).

The green revolution was made possible by the ascension of scientific plant breeding, was encouraged by a liberal democratic capitalist global society for humanitarian and national security reasons, and was then seized upon by MNC agribusiness. Grain exports and political alignment helped developing states on the international stage, but their effect on hunger and the environment are more clouded by varying degrees and definitions of success. Although marketed as a seed that would inherently provide a miraculous harvest, the green revolution HYVs were so successful because of the agricultural, social, and economic changes that necessitated them. The

seeds required chemicals and machines that had to be made by urban industry; farmers needed systems of reliable, state-sponsored credit to buy these green revolution tools; farmers were moved into urban spaces in part because of low grain prices and cheaper food options in the city made possible by American food aid; and the resulting national distribution was easier to monitor, tax, and contributed more to gross domestic production.

Ironically, the same green revolution processes lauded as miracles between 1950 and 1970, including political methods like subsidies and the ecological damage of input intensive agriculture, have led growers to be heavily criticized for their overproduction. From a state of famine, government interventions in agriculture have come to be criticized as a waste of taxpayer and state resources while the surpluses that they created are blamed for depressing commodity prices in the developing world.

Introduction

Grocery stores in the United States, with few exceptions, share similar floor plans and display items in a similar fashion. This is no coincidence,

nor is it an accident. Grocery store design is a deliberate process that is informed by a variety of factors, not the least of which is profit. Since their introduction into the American landscape, grocery stores have grown and changed in order to meet greater customer demands and increase profits. Merchants of old would hardly recognize their modern counterparts and the innovations that have been introduced, adopted, adapted, and are now commonplace in our grocery stores. They would likely be surprised to find that psychologists, anthropologists, and sociologists can be found, at one time or another, on the payroll of every major food retailer. Along with experts in marketing, sales, and advertising, social scientists have found a place in the industry determining the best way to structure a store, from the floor plans to promoting the items within, in order to yield the greatest revenue. This monograph discusses the history of American grocery store design and the factors that influence modern design. It will examine the ways in which population trends, consumer research, technological innovations, and competition have contributed to the evolution of the market, from a one-on-one interaction to something akin to a self-guided tour, concluding with a brief discussion of some of the ethical questions surrounding modern grocery store design.

Background

From the Trading Post to the Piggly Wiggly

First came the trading post; then the general store, which evolved into the neighborhood grocery store; and eventually the supermarket. In the days before supermarkets, consumers purchased items at multiple stores, such as a mercantile and general store, or directly from the source, e.g., the farmer. Certain stores carried dry goods, while others carried dairy items. The greengrocer sold produce and the butcher supplied fresh meat. It was not until the 1920s that self-service stores began to offer fresh meat, produce, and other perishable items under the same roof as dry goods.

As American cities became larger and more densely populated, the demand grew for more

efficient stores that carried a greater variety of items under one roof. Shoppers grew weary of the way that early retailers operated, with clerks measuring out bulk items for them while they waited. They were not alone in their frustration. Retailers recognized that waiting on customers was a labor-intensive process that adversely affected their revenue stream, shrinking their profit margins. The retailer's ability to wait on the customers was limited by the number of staff available, and their earning potential was, in turn, hampered by staffing costs. In short, the system was inefficient for both retailers and customers, and it was their mutual frustration that inspired the development of the self-service system upon which modern retail practices are based (Petroski 2005).

In 1916, Clarence Saunders, founder of the Piggly Wiggly stores, introduced the concept of a self-service grocery store, a precursor to the modern supermarket, wherein the nonperishable items were sold alongside perishable goods. Saunders, who was once a clerk in a general store, recognized the inefficiencies of grocery store operation. He identified high overhead and credit losses as principle issues limiting the success of retail grocery stores at the time. The highest of these costs was staffing. Before self-service, customers required assistance in order to access items, which necessitated a high staff to customer ratio, or, in the absence of such, they waited an excessively long time for service, increasing the potential for customer frustration and dissatisfaction. In response to these issues, Saunders developed and patented a three-point plan for his grocery store system, improving efficiency and the consumer experience, leading to larger profits for store operators (Petroski 2005). Elements of his plan are still an integral part of grocery store design to this day.

The first step in his plan called for an entrance/exit room or lobby. In this area, incoming shoppers would enter the store and exiting shoppers were routed to clerks who would pack customer orders and operate the cash register. Saunders later reconfigured this area in a patent issued in 1920, separating the two and making the exit room resemble today's checkout areas. Under the

original design, shoppers entering the store were met with shoppers attempting to check out, resulting in congestion that prevented incoming shoppers from easily reaching the sales floor. The new design included two checkout lanes, one that was constantly in operation and a second one on standby, to be opened in the event that the active checkout lane was overcrowded with customers (Petroski 2005).

Point two of the three-point plan addressed customer flow or circulation, with a floor design that amounted to a long, winding path along which shoppers flowed, herding customers past as many items as possible, encouraging them to linger in the store, potentially resulting in greater sales. This closed system made it impossible for shoppers to access aisles at random or to limit their visit to a few choice aisles. It was in this part of the plan that the idea of bringing perishable items into the same space as nonperishables was executed. Saunders' plan called for a glass-doored refrigeration unit in which perishables could be stored and displayed, limiting the need for shoppers to acquire those goods elsewhere (Petroski 2005).

The third and final point of the plan called for a storeroom set apart from the sales floor and a gallery of sorts, above the stacked inventory, which would allow for a clerk to observe and monitor activity on the sales floor, including the need to restock popular items. This was a departure from the old method under which storeowners would wait until after closing time to restock. No longer were sales lost because it was impossible to restock shelves and wait on customers at the same time. Introducing the concept of self-service and limiting customer-employee interaction resulted in lower overhead, which meant that the business could pass the savings on to customers by lowering prices, thereby ensuring a steady stream of customers, victory over competitors, and increased profits (Petroski 2005).

Migration and Urbanization

Most of the changes to retail practice took place on the West Coast, more specifically, Los Angeles, California, beginning in the 1920s and

1930s. The size and shape of groceries stores began to change. Supermarkets demanded more space than their pedestrian-friendly predecessors. Inside the store, there was a departure from narrow aisles and floor to ceiling shelves, making the stock more easily accessible to customers without the aid of a clerk (Longstreth 2000). The first modern supermarket, a King Kullen, was opened on the East Coast, in Jamaica, New York, in 1930 (Jackson 1995). This was the first large-scale market that resembled markets of today, with dedicated parking and affordable prices. The endeavor was so successful that within 2 years, an additional seven King Kullen markets opened in this region (Jackson 1995).

The proliferation of the modern supermarket follows the same trajectory as automobile ownership, particularly in suburban areas, and is strongly linked to class, as it was in middle-class areas that these markets were established and thrived (Longstreth 2000). When automobiles came into fashion, the drive-in or drive-through market emerged, allowing customers to shop from their car windows. The novelty and convenience of these shops facilitated the survival of certain retailers despite the changes in the retail practices seen during the mid-twentieth century. Skinner Dairy shops flourished across the southeastern United States well into the 1990s, and Dairy Barn stores are still in existence in the northeastern part of the country (Longstreth 2000). The widespread adoption of automobiles signaled the advent of the shopping strip, whole streets dedicated to retail markets that catered to the driving public, a contrast to stores of old found close to the town square or city center and conveniently located for pedestrian traffic (LeGates and Stout 2011).

Interestingly, the land parcels upon which supermarkets were built were further and further from the once prized city center. The demand for larger stores meant that storeowners needed larger pieces of land upon which to situate them. In a city setting, space was a commodity, but out along the roads that bordered city limits, there was plenty of space to be had, and much of it at a reasonable price (LeGates and Stout 2011). Commercial enterprise, specifically retail outlets like

supermarkets, is a contributing factor in the urban sprawl that is now commonplace in semi-suburban and suburban areas (Frumkin 2002).

Competition Leads to Innovation

In the waning economy of the 1970s, competition among supermarket chains was fierce and the strategy had to change once again. Competition among grocery chains led to the emergence of the “jumbo” or “superstore” in the late 1970s, with big-box stores beginning to carry groceries, in addition to housewares, clothing, etc. (Strasser 1982). In an effort to retain existing customers and lure new ones, stores became inventive in their operations. The 24-h schedule was born and the larger grocery chains began to offer non-grocery services within their stores, such as, banking, postal services, pharmacies, and later video rental (Strasser 1982). The 24-h schedule cost storeowners little extra in operation costs, since the stores were already staffed at night, albeit with stock workers and the benefit of attracting a new group of customers was profitable enough that the idea caught on. Storeowners began to enter into partnership with outside vendors and lease space in order to stay afloat. The inclusion of these services was intended to capitalize on the convenience of one-stop shopping, much in the same way that superstores had done by bringing the supermarket into the department store (War in the supermarkets 1972; Strasser 1982).

When the dust settled, after a number of mergers and closures, the retailers left standing embraced innovative thinking, and as technology evolved and computers shrunk in size, computer technology was applied in the marketplace. Point-of-sale systems were implemented in the mid-1980s, making checkout faster and more efficient (Gilchrist et al. 1982). Cashiers were no longer required to do basic math in order to make change and stores could be assured of fewer errors of this sort. These systems have been continuously improved upon over the years progressing to the point where customers could scan their own orders, further reducing staffing costs (Eskin 2005).

The introduction of online grocers to the mix of retailers sparked another round of innovative

thinking in the early 2000s. Many brick and mortar grocers have introduced a “clicks and bricks” business model in order to compete (Prasarnphanich and Gillenson 2003). This hybrid model attempts to capitalize on the best of both worlds, the familiarity of the traditional physical store experience and the convenience of the virtual buying experience. Grocers recognized the convenience of online shopping, but also knew that shopping for food is a decidedly tactile experience. It can be difficult to judge the quality of produce or meat in an online setting. These items are likely to bring shoppers into the store; however, nonperishables and non-food items can easily be purchased from an online competitor. In order to retain their base, grocers have adopted online sales in one form or another. The most common configuration allows customers to order items online and have them delivered or stop by the store and pick up the completed order (Prasarnphanich and Gillenson 2003).

Unlike the competition of the 1970s, where grocers competed with one another for business, today, they are competing with farmer’s markets, specialty stores, and stores that feature artisanal goods. In order to remain relevant, grocers have taken to creating the illusion of stores within stores. Lighting, flooring, sampling stations, and service counters are used to distinguish between departments within the grocery store. As the customer moves from one department to another, they are met with a distinctly different décor, signaling that they have entered a new “store” where specialty or unusual items are carried. The investment pays off in higher profit margins for the successful grocer (Kinsey and Senauer 1996; Nestle 2006).

Basic Principles of Grocery Store Design

Ultimately, it can be argued that there is but one basic principle of grocery store design, product placement. Circulation through the store and conveniently locating companion or complementary products are the mainstays of grocery store design, and these are achieved largely through product placement. As Clarence Saunders demonstrated in his 1916 patent application, circulation is an essential element in promoting sales.

Saunders' approach, in effect holding shoppers hostage and forcing them to pass by every item in the store until they reached the checkout counter, was effective to some extent (Petroski 2005). Modern retailers have built upon this method, achieving the same end by enticing shoppers to travel along a number of predicted paths, where high impulse items have been placed, while allowing shoppers to travel the aisles at will and in any pattern they choose. This is, however, an illusion of freedom because retailers long ago discovered, with the help of marketing experts and social scientists, that consumers could be manipulated into traveling a prescribed pathway. For example, there are certain items, staple items, like milk and bread, that bring shoppers into the store and if placed strategically, promote movement through the store along a few expected routes. Typically, these products are placed furthest from the door, ensuring that customers navigate their way through the store to that area on virtually every trip and ensuring that shoppers must traverse the store, passing numerous items and displays in order to get to their planned destination (Nestle 2006).

Convenience and coordination of complementary items goes hand in hand. Conveniently placing the hamburger buns, condiments, and chips on a display near the prepackaged frozen hamburgers is not an unusual sight. The promotion of companion items ensures that shoppers receive the message to purchase all of the elements of a meal, along with an impulse buy, in this case, the chips, thus generating additional revenue. In recent years, grocery store operators have increasingly catered to customer convenience by offering "home meal replacements" of the heat and serve variety. Meant to rival take-away and fast food outlets and capture some of the revenue lost to these establishments, stores had to be remodeled in order to accommodate refrigerated display cases that could be located away from those areas that are normally outfitted for perishables, like dairy, meat, and frozen foods. These take-away-style foods are displayed in a way more consistent with a food court than a market (Humphrey 2000; Petroski 2005). Supermarkets wanting to capitalize on special events, holidays, etc., want the flexibility to

relocate displays to various parts of the store, so as to encourage companion buying, e.g., heat and eat Buffalo wings are co-located with the carrot, celery, and blue cheese platters and carbonated beverages in a featured space within the store (Caplan 2007; Humphrey 2000).

Every aspect of the shopping experience is filled with behaviors worth studying and great attention is paid to how environment influences shopping behavior. Grocery store interiors are similar, if not identical and are meant to maximize profits by appealing to the consumer's senses. The perimeter of the store is where the most perishable items are displayed. These are also the products with the greatest profit margins, and it is in the retailers' best interest to encourage consumers to make purchases in these areas. Placing the produce section just beyond the entrance ensures that shoppers walk into an area that is brightly lit and teeming with vibrant colors. The stimulating sights prime the customer to shop, communicating that the store stocks fresh items. Larger stores will often boast a floral section and a bakery; these too will be situated very close to the entrance of the store. Taken together, the bright colors from the produce and floral sections and the scent of fresh-baked goods are a heady mix Inspiring a wave of emotion that encourages shoppers to relax and makes them feel more at home (Nestle 2006). The scent of baked goods reinforces these good feelings and stimulates the salivary glands, which has been associated with increased likelihood of spending, particularly on impulse buys. Also highly perishable, meat, poultry, seafood, and sometimes dairy, occupies the back wall of the store, so that these sections are visible to the consumer from the every aisle. Similar to the produce, floral, and bakery sections, retailers encourage spending in these areas by routing shoppers through the area or making it highly visible from anywhere in the store (Schardt 1994).

Product placement is well thought out, even within the aisles. Shelf placement is critical to both retailers and manufacturers. Items that appeal to children, such as cookies, candy, fruit snacks, and sugary cereals, are usually located at their eye level, where they can easily reach for and place

the items into the shopping cart. Bulk items and less processed foods are typically located on the highest and lowest shelves, as research shows that those for whom these products would be a priority, the items would be deliberately sought out, requiring less prominent placement (Nestle 2006). Retailers use shelf placement to maximize sales, and manufacturers, who already pay a listing fee or slotting fee to ensure that their products are carried, pay extra to ensure that their items are strategically placed. Slotting fees can cost up to \$25,000 per item, per store and manufacturers may pay several million in listing fees to supermarket chains (Nestle 2006). The aisle ends or “end caps” are prime real estate within the grocery store and manufacturers pay a premium to have their products featured in end cap displays. Contrary to popular belief, the items featured in these displays are oftentimes items that are lagging in sales, rather sale items. Customers often purchase these items mistakenly believing that they have been discounted (Nestle 2006).

From beginning to end, retailers design an environment that promotes spending. The check-out area, the last point of contact and the last opportunity to encourage customer spending, is typically populated with displays of items that are most regularly bought on impulse, such as magazines, candy, soda, and chips. The placement of these items is intended to tempt shoppers to buy something with which to occupy themselves as they wait to be checked out (Nestle 2006; Warfare in the aisles 2005).

The Psychology of Supermarket Design

Market research has shown that time pressure and the presence of other shoppers in the shopping environment influence the likelihood that consumers will visit a retail outlet, spend time in the store, and make a purchase before leaving. Time pressure is felt as the time a shopper allots for the business of browsing, selecting, and purchasing items is depleted. In the presence of low pressure, there is a direct relationship between the time spent in the store and the likelihood of purchase (Hui et al. 2009). It would seem logical that the inverse would also be true; however, such is not the case. Time pressure can lead shoppers to feel

forced to make a purchasing decision rather than allow themselves the option of leaving the store empty-handed. The increase in time pressure might make shoppers more focused in their efforts, however, reducing the likelihood that they would buy anything outside of those items that were planned purchases, thereby minimizing sales potential (Hui et al. 2009).

Shopping is a social activity of sorts. People gather in a common place for a common purpose and are often influenced by each other's behavior. The presence of other shoppers in a store or within a specific area of the store may signal to consumers that this is a preferred location or that the products attracting attention are sought after. Retailers must maintain a delicate balance, as this social influence can be a double-edged sword. The presence of other shoppers may attract more customers and encourage spending; however, there is a tipping point. Crowding has been shown to decrease willingness to visit a store and the intention to purchase, as well as actual purchasing (Hui et al. 2009).

What Is Old Is New Again

Supermarket renovation and redesign takes place, on average, every 7–8 years. It is very important for these stores to keep up with changes in the industry in order to remain competitive (Humphrey 2000). Clarence Saunders, shortly before his death in the mid-1950s, filed a patent for the precursor to the self-checkout lanes that are commonly found in supermarkets and big-box stores today. Saunders' Keedoozle was a key punch-based system that allowed shoppers to select items which were then carried by conveyor belt to the checkout and tallied up. Saunders sought to automate grocery shopping and further reduce retailers' overhead by reducing staffing costs such that only one staff person would be required to oversee a number of checkout lines. Building upon Saunders' innovations, modern retailers have moved beyond the self-checkout to the electronic shopping trolley and interactive technology in the aisles (Petroski 2005).

Patents filed for the electronic shopping trolley are among the newer developments in grocery store design. The various patents describe

variations of a shopping cart that stores consumer information and promotes an interactive relationship between the receptacle and the shopper and builds upon the basic principles of grocery store design, alerting shoppers to items they may have missed or those that complement something already in their cart. Several of the plans describe a shopping cart that can recall prior shopping trips and direct shoppers to another area of the store, where items they regularly purchase are located (Kenney 2000; Jacobi et al. 2001; Blaeuer 2002; Petroski 2005). Scanner technology has also moved away from the checkout lane into the aisles. In a process similar to that used in wedding and shower registry, retailers have been experimenting with furthering the self-service concept by equipping shoppers with handheld scanners, allowing them to keep a running tally of their order, bag it themselves, and, aside from the final, singular scan at a checkout station, have almost no interaction with store employees. Tied into kiosks in key locations throughout the store, the handheld devices allow customers to learn about a particular item or get assistance in planning a meal and even determine the best wine to accompany the meal (Eskin 2005). In keeping with previous efforts to keep customers in-house for as many services as possible, the scanners are tied into non-grocery services like the pharmacy, allowing the shopper to be notified of a filled prescription dropped off at the beginning of their visit (Eskin 2005).

Some innovations are quite literally looking outside of the box. Civil engineering and history researcher Henry Petroski, in his discussion of supermarket design, proposes a design that rejects the traditional rectangular configuration of nearly all retail outlets in favor of a circular design (Petroski 2005). Petroski posits that a radial design maximizes shopper convenience by allowing access from any aisle to any other aisle, simply by transecting the store's core. Additionally, he suggests that placing a checkout lane at the end of every aisle would be appealing to shoppers, as they could check out from wherever in the store their shopping has taken them. He further suggests that the entire edifice could be placed on a sort of turntable, allowing it to rotate such that shoppers could wait until they reached a point

close enough to their vehicle that would make exiting the building most convenient, particularly in inclement weather. Petroski filed a patent for his radial store system in 2004, but it has yet to be implemented by a retail outlet (Petroski 2005).

Ethical Questions and Dilemmas

Advances in technology have led to a reduction in brick and mortar stores and consequently a decline in the employment opportunities in the field, from entry level to management. Retailers are continually seeking ways in which to minimize overhead and increase profit. Technology has made it possible to reduce contact with store staff to a bare minimum. The advent of self-checkouts and online purchasing options further reduces opportunities for employment in this setting. The number of jobs lost in this industry over the last 20 years is staggering. Employment opportunities will continue to diminish as technology advances further with the implementation of interactive shopping carts eliminating or reducing the need for personal customer assistance. What may be beneficial to the retailer's bottom line may not be beneficial to the American economy. How do retailers ensure that they are maximizing profits without eliminating employment opportunities, especially for youth and the working poor, populations most often found in these settings? Additionally, information kiosks and interactive shopping carts might be useful in promoting the sale of complementary items, increasing profits, but will these innovations also contribute to the growing obesity problem that is front and center of American health today? Retailers may have the opportunity to play a role in the implementation of interventions that support shopping for healthy food items, but it is unlikely that the promotion of produce and whole foods will yield the same opportunities for revenue as processed food that have been linked with increasing rates of overweight and obesity.

Summary

Technology may add bells and whistles to the American shopping experience, but in the end

the same issues remain, efficiency and profit. Every innovation, every development in retail is designed to bring customers into the store, encourage them to view as many items as possible, and convince them to spend as much as possible.

Introduction

Eating food is necessary for our survival, but unlike various other things we need to do to survive – sleeping and breathing – eating can provide great pleasure. Maybe alone among the activities we need to do to survive, eating can bring us great joy.

Which ethical concerns does gustatory pleasure raise? There are the normal questions about pleasure: Is it a *good*? An *intrinsic* good? The *only* intrinsic good? *Ought* it be maximized? Are there any ethical concerns raised peculiarly by gustatory pleasure? Are there any ethical concerns especially well raised by gustatory pleasure?

This is hard to say. In our everyday lives, food is complicated because it functions at so many levels of experience, or as philosopher David Kaplan argues, “food is vexing.” In fact, Kaplan (2012) argues that the difficulty of analytically containing food explains a general philosophical neglect: “the subject quickly becomes tied up in countless empirical and practical matters that frustrate attempts to think about its essential properties (Kaplan 2012, p. 2).” This entry surveys some ethical concerns about gustatory pleasure and some responses and also some hypotheses about why these concerns aren’t more often discussed. Some of the topics we will consider include gluttony, aesthetics, puritanism, purity and pollution, and, to start, the relative lack of discussion of the ethics of pleasure.

Why So Little Discussion of the Ethics of Gustatory Pleasure? Several Hypotheses

Why isn’t there more literature about the ethics of gustatory pleasure?

Hypothesis #1

Eating is outside the realm of ethics since eating is a necessity. Hence, the pleasure derived from eating is outside that realm. It’s like breathing: No one thinks breathing raises any interesting ethical questions. No one thinks pleasure from breathing raises ethical questions. Likewise with any normal bodily function, they can’t be helped and, hence, are morally uninteresting.

Francine Prose writes,

Unlike the other deadly sins, lust and gluttony are allied with behaviors required for the survival of the individual and the species. One has to eat in order to live; presumably, the race would die out if lust were never permitted to work its magic. (Prose, p. 8)

Furthermore, one gets the impression from Prose’s book that our need to eat makes the topic of the ethics of eating uninteresting. Yet if that is Prose’s view, it is mistaken. Eating is a necessity for staying alive, but the choices we make aren’t necessary. We can pick the Whopper or the whale, the figs or the fudge. We can try to eat the yummiest foods we can or, as Prose alleges St. Francis did, go out of our way to make those foods disgusting: “According to an early biography of Francis of Assisi, the saint used ashes as a spice with which he sprinkled food in order to destroy any hint of taste (Prose 2003, p. 28).” The pleasure we get from our Whopper is not a necessity. It might be that it raises no interesting ethical issues, but, if so, that isn’t because it is something that can’t be helped.

Hypothesis #2

Pleasure comes from taste and philosophers have given taste scant attention.

As philosopher Carolyn Korsmeyer points out, in the Western intellectual tradition, taste has been given short shrift, especially compared to the attention paid to the power of sight and sound.

In this philosophical tradition, these two senses are deemed superior, “labeled the ‘cognitive’ or ‘intellectual’ senses – or in short, the ‘higher’ senses (Korsmeyer 1999, pp. 2–4).” According to Korsmeyer, the necessity of a total bodily engagement in order to taste food (or drink for that matter) is what makes this sense problematic for philosophers. Such sensual reality has made it difficult for Western philosophers to relate food to moral action, unless as an example of actions (e.g., eating and drinking) that must be *controlled* in order to achieve a moral state.

As a sociological explanation of why there isn’t much on the ethics of gustatory pleasure, this might well be compelling. But absent some grounds for thinking taste is philosophically uninteresting, it shouldn’t bar us from giving taste its due. Is the ethics of the topic of gustatory pleasure a topic worth discussing?

Hypothesis #3

Gustatory pleasure is too sensuous to be a proper subject of philosophical inquiry.

In a way, hypothesis #3 might provide a negative answer to the question above and an answer to the question of why philosophers haven’t been particularly interested in gustatory pleasure. Inquiries into the sense of taste and aesthetics have been more philosophically fruitful, but the seeming subjectivity of the gustatory taste experience has also made the topic difficult for philosophers to engage with fully. As Korsmeyer explains, “There is thus an abiding tension in aesthetic theories between the idea of taste as a sense pleasure and taste as discriminative capability: fine discernment is accomplished by means of the pleasure, yet the pleasure itself is too sensuous to count as aesthetic (Korsmeyer 1999, p. 6).” “Taste” and “tastefulness” as aesthetic concepts have primarily resided outside of bodily tastes or mediated bodily tastes through higher order aspirations. Thus gustatory pleasure and aesthetic pleasure have not been consistently linked. The problem of the body in the attainment and explanation of the aesthetic ideal haunts Western philosophy; it is no surprise, therefore, that gustatory taste suffers from philosophical neglect.

The problem of the body raises a number of issues that are also explored in *Pleasure Principle* in *Food and Taste*, *Distaste*, and *Food*.

Hypothesis #4

Pleasure is a bodily sensation and philosophers of a certain ilk – and there are numerous such philosophers – have given bodily pleasures scant attention.

Hypothesis 3 can be developed in more detail as hypothesis 4. Korsmeyer writes, “The physical necessity of eating is one of several factors that traditionally sidelined taste and food from philosophical attention in the Western tradition as eating was often dismissed as a matter of the animal ‘body’ rather than the uniquely human ‘mind’ (Korsmeyer 1999, p. 90).” For some of the philosophers in question, the body is akin to a vehicle that our immaterial souls use to make their way around the world. If this metaphysics of persons is right, attending to bodily pleasure is a bit like attending to the well-being of one’s car or bike. It’s not that it’s unimportant – it’s very important for getting around – but, rather, it’s not the sort of thing you write a philosophical book about. Moreover, so far as the concern with one’s body is just to keep it in shape to ferry the mind around, one needn’t eat *yummy* food to do so. One could eat a diet of bland, empty calories and multivitamins. (On the history of philosophers doing something like this, see Stuart (2006).) For others of the philosophers in question, bodily pleasures just aren’t as important as intellectual ones. Separating the higher pleasures from the lower, John Stuart Mill (2002) lumps a “beast’s pleasures” in with the lower and says that “a beast’s pleasures do not satisfy a human being’s conception of happiness.” Presumably, gustatory pleasure is among the beast’s pleasures. Certainly a pig enjoys its food, and, yet, Mill claims, “it is better to be a human being dissatisfied than a pig satisfied.”

As sociology, this hypothesis is quite plausible. As a justification of why little should be written about the ethics of gustatory pleasure, it leaves quite a bit to be desired.

The first defense of the hypothesis – the appeal to the thesis that the body is basically a vehicle –

depends on an extremely contentious metaphysics, one not nearly as widely endorsed in the West as in the past. Section “[The Ethics of Gustatory Pleasure: Case Studies from the Past](#)” below returns to it. The second defense – the appeal to different kinds of pleasure – grossly underestimates the pleasure of eating bacon and overestimates the pleasure of reading, say, John Stuart Mill.

Hypothesis #5

There is nothing special about gustatory pleasure. Just as pleasure from a massage or from sniffing flowers has garnered little attention because it is entirely unexceptional, so has pleasure from food garnered little attention.

Perhaps this is the most plausible hypothesis. Yet it is not fully satisfying. As Korsmeyer rightly points out that gustatory pleasure is generated by food by simultaneously engaging numerous senses, making eating and tasting food as a pleasurable experience is intrinsically more complex than massages or flowers.

Also, eating and tasting food are a much bigger part of our life than massages and flowers. In fact, it is quite unlike the vast majority of pleasures in this way. Breathing can be pleasurable, but it’s a pretty boring pleasure. Sleeping is not pleasurable (though lying in bed is). Sex isn’t necessary. Being with other people isn’t. Such acts might be necessary to having a good life, but, unlike food, they aren’t necessary to having a life at all: celibate hermits are possible. Maybe these differences between eating and, say, sniffing flowers show that there is something special about gustatory pleasures.

So there is a lack of writing on the ethics of food, and the hypotheses for why there is this lack aren’t entirely compelling justifications for why this *ought* to be the case. However, gustatory pleasure does get discussed in an ethical context from time to time, usually in the course of discussing gluttony and discussing the permissibility of killing animals for food and of gluttony.

Billions of animals are killed each year so that we can eat them. Before they are killed, they live lives containing an impressive amount of suffering. When it is permissible to kill or hurt things,

there typically is some justification for this. What justifies our killing and inflicting suffering on animals? That death and suffering is nothing to them? That we need to do so to survive? Neither is very promising. It’s striking that we raise and kill animals we enjoy eating. What role does our enjoying eating, say, cattle, play in justifying our hurting and killing cows? Is it *sufficient* justification? Or a case of giving our palate too much importance? For more on these questions, see *The Good Life for Animals*, *Animal Welfare*, and *Meat: Ethical Considerations*.

We will focus instead on gluttony. There are three main conceptions of gluttony, only two of which are tied to pleasure – those are the ones on which we focus. One conception, the one with which we won’t be concerned, is that gluttony is overeating. It’s simply stuffing oneself.

Another idea is that gluttony is overeating *that is motivated by the desire for pleasure*. So only some instances of overeating are gluttony. This is voiced by St. Thomas Aquinas when he writes,

The vice of gluttony does not regard the substance of food, but in the desire thereof not being regulated by reason. Wherefore if a man exceed in quantity of food, not from desire of food, but through deeming it necessary to him, this pertains, not to gluttony, but to some kind of inexperience. It is a case of gluttony only when a man knowingly exceeds the measure in eating, *from a desire for the pleasures of the palate* (emphasis added) (Aquinas 1964).

A third – slightly odd to contemporary ears maybe – conception of gluttony is that it is a desire for gustatory pleasure that is somehow out of whack. For example, you might desire to eat nothing but Oreos. Or you might desire meat only if served perfectly. On this conception of gluttony, overeating is no part of gluttony. In *The Screwtape Letters*, Screwtape focuses on “gluttony of Delicacy” rather than “gluttony of Excess.” The delicate glutton’s “belly... dominates her whole life” though she does not eat much (Lewis 2003, pp. 328–329). But, as with the second conception, the desire for gustatory pleasure is crucial to the sin. What is producing these out-of-whack desires is a desire for pleasure.

That gluttony – the desire for gustatory pleasure, in particular – is sinful, that is, that it is a certain sort of moral wrong, stems from three different concerns.

First, it encourages eating and then overeating and, in doing so, diverts the eater's attention away from what's important (being a good citizen, loving God) and toward food, something not important. On this, Augustine writes,

Although the purpose of eating and drinking is to preserve health, in its train there follows an ominous kind of enjoyment, which often tries to outstrip it, so that it is really for the sake of pleasure that I do what I claim to do and mean to do for the sake of my health. (Augustine 1961, p. 235)

And Aquinas writes,

The vice of gluttony becomes a mortal sin by turning man away from his last end: and accordingly, by a kind of reduction, it is opposed to the precept of hallowing the sabbath, which commands us to rest in our last end. For mortal sins are not all directly opposed to the precepts of the Decalogue, but only those which contain injustice: because the precepts of the Decalogue pertain specially to justice and its parts, as stated above. (Q[122], A[1])

The view in both passages seems to be that the pleasure we get from food turns our attention away from the fact that food is merely a tool to keep our body in good health so that we can pursue whatever it is we should be pursuing and turns our attention toward the food itself, so that we try to get ever more pleasure out of it.

When Paul complains that, for some, their god is their belly or appetite (Phil. 3: 19), it is hard to believe that gustatory pleasure isn't a large part of what is to blame. It is hard to believe God would be a belly if eating weren't so fun. For no one is God a root canal.

Besides turning us away from what should be our focus, gustatory pleasure is suspect because it is a sign of bad character. The rich man who feasts in front of Lazarus flaunts his eating (Luke 16: 19–21). Generally, some hold that enjoying one's food is an expression of gloating or meanness. William Ian Miller argues that any well-off person these days is in the rich man's boat: "[The rich man] ate... in the face of Lazarus... We, on the other hand, must exercise a bit of imagination to see the starving as we eat (Miller 1997, p. 100)." Nevertheless, he thinks the starving are there and

we indulge in the face of their starvation. To enjoy this food is to show off our bad character. For more see *Ethics and Food Taste and Gluttony*.

The pleasure we take might also be a sign to us of our own weakness. We continue to enjoy food even past the point at which we know it is good for us. Having a third helping of dessert, we continue to enjoy what we know is harmful to us.

Finally, the pleasure we get out of eating leads, some think, to significantly worse things than eating and overeating. Augustine claims, "the snare of concupiscence awaits me in the very process of passing from the discomfort of hunger to the contentment that comes when it is satisfied" (Augustine 1961, p. 235). And he writes, "The Israelites in the desert deserved rebuke, not because they wanted meat, but because in their greed for food they sulked and grumbled against the Lord" (Augustine 1961, p. 237). C. S. Lewis's *Screwtape* claims, "[Mere excess in food's] chief use is as a kind of artillery preparation for attacks on chastity (2003, p. 330)."

And the rich man in the parable of Lazarus is led by the pleasure he gets in eating to commit a crime of negligence toward Lazarus. (If the food were foul, he'd have been more likely to give some to Lazarus.) Expanding on this, Miller writes, "For that earlier economic order [eating too much – which is motivated by the pleasure of doing so –] was, in a sense, murder or a kind of criminal negligence, like drunk driving is for us (1997, p. 97)."

The Ethics of Gustatory Pleasure: Case Studies from the Past

Tea Ceremony

So the neglect of gustatory pleasure in the Western philosophical tradition is clear, in part due to the sense that yummy food does not create ethical human beings. There are cases, however, in which to engage in gustatory pleasure is understood to help attain ethical or moral virtue. And there are cases in which a consequence of pursuing moral and virtuous acts is the ability to pursue forms of gustatory pleasure. Examples of the first type of case can be found in Asian religious tradition, where the body and soul are not seen as disassociated as in the Western Christian tradition.

In the religious traditions of Confucianism, Buddhism, and Taoism, it was considered that, “by disciplining the movements and postures of the body through ritual practice, one could refine the faculties of the whole human being (Parkes 1995, p. 82).” The moral and aesthetic self are displayed through particular bodily practices and rituals. The tea ceremony is one example. The ceremony involves a number of exact and exacting gestures made by both the host and guests: the size and look of the room, the type of teacups and teapots, and the rituals of making, pouring, and drinking the tea. In a striking comparison to the Western discomfort with the body as a locus of virtue, in Japan “the practice is understood to be integral to cultivating and refining one’s essential humanity (Parkes 1995, pp. 92–93).” The entire tea ceremony focuses on aesthetic pleasures – “a time when the wind blows” – and savoring the freshly brewed tea is especially important. For more see Buddhism and Food.

Hindus

In Hindu South Asia, “good” food integrates concepts of morality and aesthetics: pleasurable food must combine moral precepts, social relations, and sensory qualities. For Hindus, the good food you prepare marks your moral standing. This involves what you use as ingredients (your respect of the environment), those with whom you share your food (your similarity and difference with others), and your gifts of food (to people and to gods). For example, food offerings have long been a gift to the gods, an important component of religious ritual, both in people’s domestic shrines and at the large pilgrimage sites or temples for the gods. Offerings of sacred food, or *Prasad*, are particularly powerful for in Hinduism “food is an inherently moral substance (Toomey 1986, pp. 55–56).” In a continuing practice through today, Hindu pilgrims offer *Prasad* to the deity and eat the leftovers; among devotees of Krishna, this food offers moral enhancement and gustatory enjoyment. For more see Hinduism and Food.

Land of Cockaigne

And then there is the notion that moral virtue will be *rewarded* with gustatory pleasure. This is

exemplified in the medieval period in Europe. In medieval Europe, tales of the Land of Cockaigne were extremely popular, an important oral and written story that created a fantasy of a place somewhere on earth that always involved two promises: “Work was forbidden, for one thing, and food and drink appeared spontaneously in the form of grilled fish, roast geese and rivers of wine (Pleij 2003, p. 3).” This was a paradise on earth that transformed the sufferings of everyday life into an endless sea of pleasures, and the basic need for food becomes a desire constantly fulfilled. One version of the tale includes this description: By anyone old, young, weak, or strong./There no one suffers shortages;/The walls are made of sausages./Windows and doors, though it may seem odd,/Are made of salmon, sturgeon, and cod./The tabletops are pancakes. Do not jeer,/For the jugs themselves are made of beer (Pleij 2003, p. 33). This world was not only worry-free but also allowed for pleasures without the requirements of virtuous actions expected by the Catholic Church. The Land of Cockaigne resolves the long-standing question of whether gustatory pleasure somehow transgresses or undermines virtue by making it easy to both have food and enjoy the taste of it. Interestingly, Marion Rombauer Becker, coauthor of *The Joy of Cooking* (with her mother Irma Rombauer), named her country home “Cockaigne” and subsequently her favorite recipes followed suit, e.g., Brownies Cockaigne and Fruit Cake Cockaigne.

Brillat-Savarin

By the 1800s, the dialogue about necessity and pleasure in Europe had expanded beyond the confines of religious virtue and incorporated Enlightenment principles of rationality and individuality. Jean Anthelme Brillat-Savarin’s work *The Physiology of Taste* was first published in 1825 and has been continuously in print ever since (including multiple editions in English). Brillat-Savarin was a philosopher of the French Revolution who argued that the pleasures of the table were now available to all social classes, another example of the benefits of democracy. For him, the pursuit of gustatory pleasure was a hallmark of any civilized person, a democratic principle. In one of his famous aphorisms that begin his book, Brillat-Savarin claims that “The

Creator, though condemning man to eat to live, invites him to do so by appetite, and rewards him by enjoyment (Brillat-Savarin 1970, p. xxxiii)." He names such a pursuit of enjoyment "gastronomy" and argues that if foods (and drink) are defined by their simultaneous ability to provide pleasure, nourishment, and virtue, civilized gastronomes rather than barbarous gluttons can be cultivated: "Gastronomy considers taste in its pleasures as well as in its pains. It has discovered the gradual degrees of excitation of which it is susceptible; it has rendered their action more regular, and laid down limits that a man who respects himself should never overstep (Brillat-Savarin 1970, p. 27)." In the modern period, Brillat-Savarin's new interpretation of gustatory pleasure as gastronomy rather than gluttony (*gourmandise*) has become more prevalent. For more see Brillat-Savarin and Food.

The Ethics of Gustatory Pleasure: Case Studies from the Present

In a recent essay, *Ethical Gourmandism*, Korsmeyer explicitly addresses the tension between ethics and pleasure when considering "tasty morsels." Borrowing on works of "ethical criticism" in evaluation of art, Korsmeyer asks, "is the very taste of the food we eat imbued not only with flavor but with moral valence? (Korsmeyer 2011, p. 89)." Focusing on taste sensation, she uses recent research in psychology to point out that taste sensations are never solely bodily experiences but are always mediated by moral and other concerns. She disagrees with Kent Bach's argument that a pleasurable taste experience can occur distinctly from knowledge of what the food is, where it is from, or how it is produced, writing, "my inclination is to believe that such separation is not only difficult but impossible (Korsmeyer 2011, p. 97; Bach 2007)." That is, one's *judgment about the ethics and aesthetics of what one eats modifies* the pleasures one gets from that food. Bach's position is that this is not so.

Korsmeyer's *dialectic* between the virtues of a food or drink and the pleasure derived from consuming that food or drink illuminates recent interventions into the modern industrial food system. The argument for virtuousness is often paired with

discussions of the yumminess of foods due to the moral means of production, manufacture, distribution, etc. (For more see Jefferson's Moral Agrarianism and Eating and Environmental Sustainability.) Part of the locavore ideology is that knowledge of where one's food comes from increases how much one enjoys it. Knowledge comes from details about the aims of how the food should be made and the process by which that occurs: organic, local, artisan, fair trade, healthy, and sustainable are all concepts addressing this need to know. There are also particular types of foods labeled as good or virtuous: whole fruits and vegetables and grass-fed meat are examples. In the movement for changing the contemporary food system, this righteous insistence tends to revolve around a dichotomy between "good" and "bad" foods (Heldke 2011).

Thus, though it is tempting to see the new dialectic between the ethics and aesthetics of food and drink as a possible resolution to the long-term philosophical neglect of gustatory pleasure, pitfalls remain. Political philosopher Wendy Brown, in an analysis of the changing shape of political movements since the 1970s, makes a distinction between morality ("ethical wisdom") and moralism, arguing that moralism tends to adopt a "righteous insistence on knowing what is True, Valuable, or Important" (Brown 2001). A strong current of moralism exists in the food movement.

Part of the ideology of proponents of free-range farming is that food that is morally impeccable is also the yummiest. Dan Barber and Michael Pollan both argue that there is no need to choose between ethics and taste. (This functions as a response to the common claim that vegans must not like food very much: what's implicit in that common claim is that what the vegans think is ethical is not particularly delicious.)

Barber and Pollan might be right. Their being right would depend, of course, on what's delicious and what's morally unimprovable. A different line was taken by Thomas Keller and Andoni Luis Aduriz. In a 2012 *New York Times* article, Julia Moskin writes,

Keller and Aduriz are united in the belief that their responsibility as chefs is primarily to create breathtakingly delicious and beautiful food—not, as some of their colleagues think, to provide a livelihood

for farmers near their restaurants, to preserve traditional culinary arts or to stop the spread of global warming. . . .

When it comes to supporting communities, [Keller] said, he chooses to support Stonington, Me., by buying exquisite oysters from a seafood dealer there. There are oysters on Long Island, of course, but Mr. Keller believes that his priority has to be taste, above all other considerations like sustainability, seasonality and food miles.

“Is global food policy truly our responsibility, or in our control?” he asked. “I don’t think so (Moskin 2012).”

Basically, their job is to produce what is delicious, ethics be damned. Their view seems to be closer to Bach’s than Korsmeyer’s and to be indifferent to whether Barber and Pollan are right. Keller’s query as to the responsibilities of a high-end chef introduces the emerging problem of this particular dialectic between ethics and aesthetics. The “ethical” person who also gets to eat “yummy” food is first and foremost a *consumer*. These ethical acts are really economic purchases that happen to also provide calories to nourish our bodies. The modern dilemma about food is no longer the mind/body dualism, but the consumer/producer paradox. Wendell Berry calls it “industrial eating.” For Wendell Berry, the industrial eater is an alienated consumer who no longer takes the time to even really savor his food, let alone have an engaged relationship with the virtues of certain types of food production. For more see Jefferson’s Moral Agrarianism.

Summary

This entry has focused on the ethics of gustatory pleasure. Pleasure plays another role in food ethics. It was because animals are capable of pleasure – and also capable of pain – that utilitarians like Bentham and Mill argued that they should, as a rule, not be made to live nasty lives.

Although the continuing conflicts between food, pleasure, and ethics may or may not bode well for a clearly elaborated argument as to the ethics of gustatory pleasure, clearly more and more people, scholars included, are finally

engaging with an ethics of pleasure that does incorporate the sensual elements of taste.

Introduction

Herbicide-resistant (HR) crops have been genetically modified (GM) so that they are not damaged by applications of certain herbicides. Because herbicides are designed to kill plants, they can cause injury to conventional crop varieties. This limits when and how herbicides can be applied, making them less effective. Because many herbicides are effective against only certain types of plants, growers face the complexity of choosing among several chemicals for different weeds. Crops resistant to broad-spectrum herbicides overcome these problems by reducing crop injury and allowing applications of a single herbicide for

most (or all) chemical weed control (NRC 2010). Mechanical and hand tillage to control weeds has become more costly as labor and fuel costs have risen relative to herbicide costs (Osteen and Fernandez-Cornejo 2013). There are additional environmental problems with tillage, especially on highly erodible land. Erosion can reduce the long-term productivity of soils and profitability of farming. Sediment from erosion can also reach water bodies contributing to various environmental problems (Fernandez-Cornejo and Caswell 2006).

HR Crop Adoption

Genetically modified HR crops first became available in the mid-1990s. GM HR crop varieties have been developed for a number of crops but require national regulatory approval before they can be commercially planted. Varieties of HR alfalfa, canola, cotton, maize, soybeans, and sugar beets have been commercially planted in a number of countries. In countries where they have been approved, HR varieties have been extensively adopted, with acreage often exceeding that for non-GM varieties. HR cotton and soybean varieties now account for the majority of global acreage of these crops (Frisvold and Reeves 2010). Most HR crop acreage is planted to glyphosate-resistant (GR) varieties. Because the herbicide glyphosate controls more than 300 weed species, growers can control many broadleaf and grass weeds effectively using one herbicide instead of many different ones.

Adoption of HR crops has been rapid despite mixed evidence that they increase farm profits (Bonny 2011; Fernandez-Cornejo and Caswell 2006; Marra et al. 2002; NRC 2010). Researchers have suggested that HR crops provide benefits difficult to capture using standard farm profit estimates such as simplification of weed management decisions, convenience, increased flexibility in timing, reduced crop damage, lower environmental risk, lower management time requirements, and compatibility with conservation tillage. These hard-to-measure

benefits may account for rapid HR crop adoption (Bonny 2011; Fernandez-Cornejo and Caswell 2006; Frisvold and Reeves 2010; Marra et al. 2002; NRC 2010, 2012). Weed resistance to herbicides other than glyphosate may also account for the popularity of GR varieties.

GR crops have been credited with two types of environmental benefits: encouraging adoption of conservation tillage and substitution to herbicides with lower toxicity and persistence in the environment (Fernandez-Cornejo and Caswell 2006; Green 2012; Kleter et al. 2007; NRC 2010, 2012; Norsworthy et al. 2012; Price et al. 2011). The empirical support for the complementarities between GR crops and conservation tillage is stronger than for herbicide substitution. Because conservation tillage reduces the number of machine passages over the field, it reduces fuel use. It thus contributes to soil carbon sequestration and reduced carbon emissions from fuel use. Conservation tillage can reduce sediment and chemical runoff, reducing water pollution. The US National Academy of Sciences reports, however, that further research is needed to measure and document contributions of HR crops to area-wide improvements in water quality (NRC 2010).

While HR crops have also been credited with reducing environmental risks of herbicide applications, attributing changes in environmental risks to HR crop adoption is difficult (Bonny 2011). Simple comparisons of herbicide use before and after HR crops became available are not appropriate for assessing the impacts of HR crops on herbicide use. First, many things have changed since the mid-1990s when these crops were first adopted. These include changes in hectares planted, output and input prices, agricultural policies, and weather. Estimates of the effect of HR crops on herbicide use must control for these factors. Second, growers are not randomly assigned to adopter and non-adopter groups in controlled experiments. Growers choose whether or not to adopt HR crops. If adopters have fundamentally different characteristics than non-adopters, comparing herbicide use across the two groups will suffer from sample selection bias (Fernandez-Cornejo and Caswell 2006). Third,

kilograms of active ingredient applied are not good measures of the environmental impact of herbicides. Herbicides vary in their toxicity to different species, persistence in the soil, half-life, leaching potential, and runoff potential, which can have ecological effects as well as impacts on farm workers and consumers (Bonny 2011). A number of studies have attempted to address this issue by weighting herbicide applications by factors such as mammalian toxicity, soil half-life, or the more comprehensive Environmental Impact Quotient (EIQ) (Kovach et al. 1992) that attempts to account for multiple risks (e.g., Bonny 2011; Kleter et al. 2007). Compared to many other herbicides for which it substitutes, glyphosate has lower toxicity and persistence in the environment. This means a switch to glyphosate-based weed management may reduce environmental risks, even if total kilograms of active ingredient applied increase. US herbicide data suggests that kilograms of glyphosate applied have increased substantially since the mid-1990s, while kilograms applied of many other compounds have decreased.

The most widely cited estimates of grower shifts in herbicide use, however, have come from expert surveys of extension specialists, not from actual farm-level data. In these analyses, specialists provided assessments of likely or recommended herbicide treatments that farmers would have made if they did not plant HR crops. Studies have extrapolated expert survey estimates to national changes in herbicide use, weighting herbicide use based on EIQ measures (e.g., Green 2012; Kleter et al. 2007). Studies adopting this approach show a decline in the EIQ attributable to HR crop adoption. The expert-survey approach can be a cost-effective way to conduct an *ex ante* assessment of the *potential* environmental impacts of HR crops. These estimates, however, do not produce statistically valid estimates of actual herbicide use, let alone estimates of changes in herbicide use attributable to HR crop adoption. In some cases, careful statistical analyses of farm-level HR crop adoption and herbicide use corroborate the expert survey results, but in other cases, not.

Reduced Diversity of Weed Control Tactics Leads to GR Weeds

A fundamental means of delaying the evolution of weed resistance is to diversify control strategies (Duke and Powles 2009; Norsworthy et al. 2012; Vencill et al. 2012). This can be accomplished by using nonchemical control methods (such as tillage, row spacing, and crop rotations) along with chemical control. If herbicides are used, avoiding reliance on herbicides with the same mechanism of action (MOA) is crucial. The widespread adoption of GR crops in the United States, however, has led to a pervasive reduction in the diversity of weed control tactics. Growers have relied less on nonchemical control methods and have relied heavily on a single mode of action for chemical control (Frisvold and Reeves 2010; Norsworthy et al. 2012).

Before the introduction of GR cotton, maize, and soybean varieties in the United States, glyphosate use on these crops was limited. Since the introduction of GR crops, there has been a narrowing of herbicides and herbicide MOAs used for all three crops, which greatly increased the selection pressure for herbicide resistance. From 1997 to 2010, glyphosate's share of total kilograms of herbicide active ingredient applied to maize rose from 1% to 35%. For cotton, this share rose from 3% to 62% from 1995 to 2010, while for soybeans, it rose from 11% to 89% from 1995 to 2006. Three factors contributed to reliance on GR crops and glyphosate. First, there was increasing resistance to MOAs that had been in general use for a long time, such as acetolactate synthase (ALS – B2) and photosystem II (Cs) herbicides. Second, glyphosate became attractive as a post-emergence herbicide because of its broad-spectrum efficacy and reliability. Low cost was also a factor after the patent on glyphosate expired in 2000 (allowing lower cost generics on the market). Third, herbicides with new MOAs have not been registered in the United States since 1998. Phosphinic acid herbicides such as glyphosate accounted for 60% of hectare treatments for cotton in 2007 and 77% of hectare treatments for soybeans in 2006. By 2005, triazine and phosphinic acid treatments in maize accounted for two-thirds of hectare treatments.

Evolution of Glyphosate-Resistant Weeds

Increased reliance on GR crops and glyphosate as the dominant means of weed control generated enormous selection pressure GR weeds. Before 1998, there were no reported glyphosate-resistant (GR) weed species in the United States. By 2013, however, glyphosate resistance had been confirmed for 14 species in the United States spread across 36 US states (Heap 2014). GR weeds have proven problematic for cotton, soybeans, peanuts in rotation with cotton, maize, and in California, perennial crops. Resistance to glyphosate has evolved in Palmer amaranth (*A. palmeri*) in GR cotton fields throughout the Southeast United States. Costs of GR weeds can be significant, ranging from \$5 to \$130/ha (Norsworthy et al. 2012). In severe cases, growers may opt to abandon fields altogether.

Barriers to Resistance Management

Problems with GR weeds have raised questions about the sustainability of GM HR crops. While many growers are adopting many Best Management Practices (BMPs) to manage weed resistance, adoption rates for a number of practices remain low. While resistance management practices for insect-resistant Bt crops are federally mandated in the United States, management of weed resistance for HR crops has been voluntary (Frisvold and Reeves 2010). Bt crops have pesticides incorporated into them and are thus regulated under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA). The current rate of BMP adoption has proved insufficient to delay resistance in many areas (NRC 2012). Slowing resistance implies economic and environmental trade-offs (Frisvold and Reeves 2010; Norsworthy et al. 2012; Price et al. 2011). For growers, BMPs may entail reductions in short-run returns. No-till and reduced tillage practices have provided a number of environmental benefits that could be lost if growers revert to tillage in the face of weed resistance. Using herbicides with a different MOA than glyphosate may also delay resistance. This, however, may entail using more

herbicides and using herbicides with greater persistence or toxicity than glyphosate. Thus, some of the practices to delay resistance to glyphosate may undercut some of the environmental benefits of glyphosate.

As of the mid-2000s, many growers held attitudes and perceptions that would discourage BMP adoption (NRC 2012). A significant share of growers appeared unaware of certain major factors contributing to the evolution of weed resistance. Many growers may attribute infestation and spread of resistant weeds to factors beyond their control such as natural forces (e.g., wind, birds, animals) or poor weed management by their neighbors. If growers perceive that preventing weed resistance is beyond their individual control and requires collective grower action, they will have less incentive to take individual actions that incur additional costs to delay resistance. Growers may also believe that new chemistries or cultivars will soon become available to address resistance problems. Growers have less incentive to conserve the efficacy of an herbicide if they believe substitutes will be available in the future.

Role and Limits of Stacked Trait HR Varieties

One approach to address resistance to GR crops is through plant breeding by “stacking” resistance traits to multiple herbicides in individual crop varieties (Green 2012). Resistance can, in theory, be delayed by rotating between herbicides with different MOAs and by using herbicide mixtures. This would reduce selection pressure on any one compound. If a particular weed were resistant to one herbicide, it may be killed by another herbicide that relies on a different MOA. Companies are developing new crop varieties that combine glyphosate resistance with resistance to herbicides with different MOAs (Green 2012). One example will be varieties that stack glyphosate resistance with resistance to different ALS-inhibiting herbicides. Varieties resistant to two more herbicides will soon be commercially available (Green 2012). These stacked varieties will be combined with homogeneous blends (herbicide mixtures with different

MOAs). Because these blends will be mixtures of currently registered herbicides, they may receive regulatory approval relatively quickly.

Combining herbicide mixtures with multiple-resistant (MR) crop varieties can reduce reliance on a single MOA. This strategy also avoids the high cost and lengthy delays in developing novel herbicides. It raises questions, however. First, how many different MOAs need to be combined in one HR crop variety to delay resistance substantially? How is the potential for delay affected by the fact that some weeds are resistant to the herbicides that are to be combined. For example, some weeds are already resistant to glyphosate, others are resistant to ALS inhibitors, and some are resistant to both. The list of weeds resistant to multiple herbicides continues to grow (Mortensen et al. 2012; Heap 2014). Some have criticized this MR strategy because it may lead to greater herbicide use and negative environmental impacts in the short run and divert attention and resources away from more comprehensive integrated weed management research and extension (Mortensen et al. 2012).

Summary

Since their introduction in the mid-1990s, growers have adopted genetically modified, herbicide-resistant (HR) crop varieties quickly in countries where they have been approved. Benefits to growers not captured in standard farm profit calculations appear to account for the popularity of HR varieties. HR crops have been credited with encouraging adoption of conservation tillage and causing substitution to herbicides with lower toxicity and persistence in the environment. Evidence for the effect on conservation tillage is stronger than evidence for herbicide substitution. Adoption of HR crop varieties led to a dramatic reduction in the diversity of weed control tactics in US agriculture and the evolution of HR weeds. Grower adoption of resistance management strategies has been limited and insufficient to delay resistance. Development of crop varieties resistant to multiple herbicides is being pursued as a strategy to respond to HR weeds. Debates remain over the

potential of this approach relative to a more comprehensive integrated weed management strategy to successfully delay resistance.

Hinduism and Food

Colleen Taylor Sen
Chicago, IL, USA

Introduction

The concepts of ahimsa, noninjury to all forms of life, and the associated practice of vegetarianism were born on the Indian subcontinent in the sixth century BCE. Initially adopted by the upper castes of society, they became more widespread with the spread of devotional movements starting in the sixth century CE. In the twentieth century, vegetarianism was one of the core teachings of the great political and spiritual leader Mahatma Gandhi. While today a minority of Indians are strict vegetarians, vegetarianism remains an ideal of society.

Definition of Hinduism

Hinduism is the world's third largest religion (after Christianity and Islam), with an estimated 950 million adherents in India and the diaspora. Although some beliefs and practices are thousands of years old, the term "Hinduism" is relatively new. It was first used in the ninth century CE by Central Asians and Persians for the inhabitants of the subcontinent. (The word comes from the Persian Sindh, meaning the land on the banks of the Sindhu, the Indus River). In the late eighteenth century, Europeans began applying it to the followers of indigenous Indian religions. Until then, Hindus (if they called themselves anything) referred to themselves as followers of the *Sanatana dharma*, the eternal *dharma* – a Sanskrit word variously translated as duty, personal path, vocation, law, and religion.

Unlike Islam or Christianity, Hinduism has no founder, no credo, and no scriptures that are recognized by all adherents. It is a conglomeration of various philosophies, beliefs, and social norms that have evolved over the millennia. As K. M. Sen writes in his history of Hinduism:

Hinduism is more like a tree that has *grown* gradually than like a building that has been *erected* by some great architect at some definite point in time. It contains within it . . . the influences of many cultures, and the body of Hindu thought offers as much variety as the Indian nation itself (Sen 1991, pp. 4–5).

Nonetheless, there are some attitudes and practices shared by many Hindus, especially related to food. According to ancient Indians texts, of all things created, food is the most important since it enables a person to use all his faculties and frees him or her from ignorance and bondage. "Purity of thought depends on the purity of food," said the ancient sages, or, to use the modern phrase, "You are what you eat."

Historical Background: The Indo-Aryans

The oldest text revered by Hindus is the *Rig Veda*, a collection of hymns and paeans to the gods, incantations, prayers, and philosophical

speculations composed between 1700 and 1100 BCE. This and other works, collectively called the Vedas, were passed down orally and written down in Sanskrit centuries later. Even today, some of the verses are recited during weddings and funerals, making it one of the world's oldest religious texts in continuous use.

It was composed by people known as Indo-Europeans or Indo-Aryans, who migrated in small groups to the subcontinent from the region between the Black and Caspian Seas between the fifth and fourth millennia BCE. The Indo-Aryans were pastoralists, whose main occupation was raising cows. Their gods were forces of nature with counterparts in classical Greece and Rome: Indra, the equivalent of Zeus and Jupiter, ruled over the sky and heavens; Agni was the god of fire; Varuna, the god of thunder; etc.

Life and nature were uncertain, and the main way of placating the gods and winning their favor was by rituals that involved animal sacrifice. Various animals were killed by the priests, called Brahmins, who alone knew the complicated rituals associated with the sacrifice. After the meat was offered to the gods, it was consumed by the priests and worshippers. Similar rites took place in classical Greece, Rome, and Persia.

Although meat eating was condoned, the ancient texts show a certain ambivalence about eating meat, especially cows. Some recommend the offering of effigies of animals made of ghee or clarified butter, vegetables, or rice and barley in place of meat. Cows were held in very high esteem in Indo-Aryan society. A hymn in the *Rig Veda*, "A Glorification of the Sacred Cow as Representing the Radiant Heavens," declares:

The Cow is Heaven, the Cow is Earth, the Cow is
Vishnu, Lord of Life
Both Gods and mortal men depend for life and
being on the Cow.

By around 1000 BCE, social divisions had become sharper, and there emerged one of the most distinctive features of Indian society, the caste system. At the top were the Brahmins. Next were the *rajanya* (later called *kshatriya*), the warriors and rulers, followed by the *vaishya*, the providers of wealth through herding,

agriculture, and trade. The fourth category, the *shudra*, was artisans and service providers. Later a fifth category was added for people who did jobs that even shudras would not touch, such as tanning hides, collecting garbage, or burying the dead. These were the outcastes, today legally referred to as scheduled castes.

Over the centuries, caste came to have many ramifications, especially for the two most fundamental human activities, sex and eating. People were not supposed to marry, accept food from, or eat with someone outside their caste. Caste also became associated with ideas of purity and pollution, with the Brahmin considered the purest of the pure. Contact with lower castes was considered polluting, and there were elaborate rules governing such contacts.

Reform Movements

Starting around the beginning of the first millennium BCE, the Indo-Aryans moved eastward to the site of modern Delhi and Bihar and westward into present-day Gujarat. They settled down, built towns and cities, and developed a sophisticated urban civilization. Wealth and leisure gave rise to philosophical, moral, and religious speculation, and new ideas emerged that became an integral part of Hindu thought. One is that there is an endless cycle (*samsara*) of death, rebirth, redeath, etc., and that souls are constantly reborn (reincarnation). From this emerged the law of *karma*, a word which means action or deeds, with the connotation of morally charged action, good or bad. The sum of a person's past karma determines how he or she is reborn into his present life.

These ideas were central to two new religious/philosophical movements, Jainism and Buddhism, which arose in the sixth century BCE. Their founders, Mahavira and Gautama Buddha, respectively, were the sons of rulers who abandoned their palaces to seek the meaning of life. Both preached the doctrine of *ahimsa* – a Sanskrit word meaning noninjury or nonviolence – and rejected animal sacrifice. Buddha, who advocated a more moderate path to salvation, allowed his lay

followers to eat meat. Buddhist monks had to follow a vegetarian diet in their monasteries, but outside, where they begged for their food, they had to accept anything that was given to them, even meat or fish, provided that the animal was not slain on purpose for the monk and the recipient did not see, hear or even suspect the killing of the animal.

Jainism was much stricter. Five things were and are absolutely forbidden to all Jains, laypeople, and monks alike: meat and meat products, fish, eggs, alcohol, and honey. In addition, monks and nuns and devout Jains were not allowed to eat vegetables and fruits that grew underground or contained the seeds of life, including potatoes, figs, pomegranates, etc.

Both Buddhism and Jainism rejected the authority of the Vedas, the dominance of the Brahmins, the ritual sacrifice, and the caste system. These practices won many followers among common people and rulers alike. In addition to the ethical and moral reasons for avoiding meat, there were economic issues. Some sacrifices required hundreds of animals, which placed a great burden on the farmers who had to donate their animals for this purpose. The rulers' growing administrative and military costs competed for the funds demanded by the Brahmins for their expensive rituals. The stabilization of agriculture made cattle more useful for various operations, such as plowing and making manure, which was used as a fertilizer and, when dried, as a fuel (*gobar*, still a cooking fuel among the poor in India).

The Brahmins recognized the popular appeal of Jainism and Buddhism and co-opted many of their doctrines and beliefs. The eating of beef became taboo, and vegetarianism began to be adopted as a high ideal, a signifier of "purity," and a marker of status. As one scholar notes, "Vegetarianism was far more than an interesting new dietary custom; it was the focal point of what might be called a revolution of values" (Smith 1990, p. 197).

A political boost to vegetarianism was given by Emperor Ashoka Maurya (304–232 BCE), to this day considered the greatest of all Indian rulers, revered not only for his conquests but his efficient administration and tolerant policies.

A supporter, if not an adherent, of Buddhism, Ashoka advocated ahimsa, prohibited animal slaughter and meat consumption in his empire on certain days, and virtually abandoned the consumption of meat in his own court. A famous inscription reads:

Formerly, in the kitchens of the [emperor], several hundred thousand animals were killed daily for food, but now at the time of writing only three are killed – two peacocks and a deer, though the deer not regularly. Even these three animals will not be killed in future.

Moreover, the climate and fertility of India meant a year-round abundance of fruits and vegetables which facilitated the avoidance of meat. Finally, these trends were no doubt reinforced by an affection similar to that we show towards our domestic pets. The thought of eating dogs horrifies people in the Western world, although most people have little compunction about eating cows.

The Dharma Texts

Between 300 BCE and around 500 CE, Sanskrit texts called the *dharmasutras* and *dharmashastras* laid down rules for all society, so that each person could live according to his or her *dharma*. Many of their prescriptions and proscriptions concern marriage and food. There are lists of permitted and banned foods for the higher castes, including garlic, onions, mushrooms, the milk of cows who have calved, domesticated fowl and pigs, most fish, meat from a slaughter house, alcohol, and cows. Some foods were proscribed for people at different stages of their lives. Students, for example, should avoid meat, honey, spices, onion, garlic, and sour foods that are supposed to be sexually stimulating. An old man is supposed to retire to the forest as a hermit and live on fruits, vegetables, roots, flowers, and wild grains.

The texts are, however, contradictory with respect to meat. Members of the higher castes were permitted to eat meat under certain circumstances: during certain rituals, for example, or when their life is in danger. The Manusmṛiti, one of the most influential and oft-quoted shastras,

devotes an entire section to the pros and cons of eating meat. The discussion opens and closes with statements defending the ancient tradition of eating meat for sacrifices. But they bracket passages favoring vegetarianism and nonviolence and condemning meat consumption outside of the sacrifice, with the number of antimeat verses outnumbering pro-meat verses by 25–3. Manu ends firmly on the fence by declaring “There is nothing wrong in eating meat nor in drinking wine nor in sexual union, for this is how living beings engage in life, but abstention bears great fruit.”

These contradictory attitudes reflect continued tensions in Indian society between the traditions of the Brahmins, whose power was based on the sacrifice, and popular support for vegetarianism. That it was becoming widespread is evident in the statement of the Chinese Buddhist Fa Hsien who visited northern and eastern India in the early fifth century CE. He wrote:

Throughout the whole country the people do not kill any living creature, nor drink intoxicating liquor, nor eat onions or garlic. The only exception is that of the Chandalas [outcastes]. . . . In that country they do not keep pigs and fowls, and do not sell live cattle; in the markets there are no butchers’ shops and no dealers in intoxicating drink. . . . Only the Chandalas [outcastes], fishermen and hunters, and sell flesh meat. (Acharya, p. 147)

As the last sentence indicates, meat consumption had increasingly come to be associated with low status, although an exception was made for kings and chieftains, for whom hunting was a way of life.

The Devotional Movement

By the end of the sixth century CE, a new form of worship emerged, often called *bhakti*, which means devotion. It was based on a personal relationship between the worshipper and a loving deity. The sacrifice was replaced by *puja*, a ceremony in which the worshipper offers flowers, fruit, and grains to the image of a deity either at home or in a temple. The Bhakti movement was initially resisted by the Brahmin priests, but they eventually adopted the practices and presided over the ceremonies. By the eleventh or twelfth

century, the movement had spread throughout South Asia. The two main deities were Shiva, the god of creation and destruction, and Vishnu, the god of preservation, and they remain so today.

Vishnu had many incarnations, including Rama, hero of the Ramayana, and Krishna. Worshipers of these deities are called Vaishnavs. Many Vaishnavs were and are vegetarians, and some even live in monasteries, where they follow a vegetarian diet. Worship of Krishna became very popular in the sixteenth century under Sri Chaitanya (1486–1534) and spread all over northern and eastern India. Born into a Brahmin family of Vedic scholars, Chaitanya rejected the strict hierarchy and cruel discrimination of the caste system and preached a message of equality and love. He drew an enormous following among the lower castes, who emulated his habits, including his vegetarianism.

A modern descendent is the International Society for Krishna Consciousness (ISKCON), known popularly as the Hare Krishna movement, founded in New York City in 1966, whose members follow a lactovegetarian diet, including many sweets made from milk and sugar. This is related to the origins of Krishna (also known as Govinda, the divine herdsman), who was raised by dairy farmers and as a child played with the gopis (milkmaids) and stole butter from the local farmers.

In the *Bhagavad Gita*, considered one of the central texts of Hinduism, Krishna describes three basic dharmas or natures: *sattvic*, which can be translated as lucidity, purity, or dispassion; *rajasic*, translated as passion, distraction, or restlessness; and *tamasic*, dark inertia or dullness, which is manifested in sloth, lethargy, anger, and ignorance. He says:

Foods that please lucid men
Are savory, smooth, firm and rich
They promote long life, lucidity
Strength, health, pleasure and delight
Passionate men crave foods
That are bitter, sour, salty, hot
Pungent, harsh and burning
Causing pain, grief and sickness
The food that pleases

Men of dark inertia is stale,
 Unsavory, putrid, and spoiled,
 Leavings unfit for sacrifice.

The nature of these foods is described in other texts, especially those associated with hatha yoga, and yogis (practitioners of yoga) are still required to eat sattvic foods. They include rice, barley, wheat, fresh fruits and vegetables, especially green leafy vegetables, green lentils, milk, fresh yogurt, almonds, seeds, sugar candy, dry ginger, cucumber, and ghee. Rajasic foods include fermented foods that have not been freshly made, cheeses, some root vegetables, fish, eggs, salty, sour and hot items, coffee and tea, white sugar, and spices. Tamasic foods include leftovers that have been around more than a day, canned and preserved foods, fast foods, fried foods, and processed foods as well as meat, tobacco, alcohol, and drugs. These categories also had strong associations with caste: sattvic foods were supposed to be eaten by Brahmins, rajasic by kshatriyas, and tamasic by outcastes.

The Influence of Mahatma Gandhi

The great Indian political leader Mohandas Karamchand Gandhi (1869–1948), known as Mahatma (“great soul”), was a very strong advocate of vegetarianism. His extensive writings on food, morality, and ethnics reflect both traditional Indian food theories and practices and modern nutritional science. Gandhi’s beliefs about food are inseparable from his philosophy which was based on *ahimsa*, or nonviolence, and *satyagraha*, a Sanskrit word that means “insistence on truth.” Translated into political terms, it meant strength and determination in achieving one’s political goals – in this case, Indian Independence – by nonviolent methods. Restraint of one’s palate was one of the ways of strengthening one’s character.

Gandhi was born into a Vaishnav Hindu family in Gujarat in an area with a strong Jain presence. His family was vegetarian and his pious mother often fasted. When Gandhi was a teenager, a friend persuaded him to try meat. At the time

there was a popular belief that the British owed their strength and dominance to their consumption of meat and that if Indians followed suit, they could defeat the British and win independence. A popular Gujarati poem went,

Behold the mighty Englishman
 He rules the Indian small,
 Because being a meat-eater
 He is five cubits tall.

In his autobiography, Gandhi described his first foray into meat eating:

So the day came. It is difficult fully to describe my condition. There were on the one hand, the zeal for ‘reform’, and the novelty of making a momentous departure in life. There was, on the other, the shame of hiding like a thief to do this very thing. I cannot say which of the two swayed me more. We went in search of a lonely spot by the river, and there I saw, for the first time in my life – meat. There was baker’s bread also. I relished neither. The goat’s meat was as tough as leather. I simply could not eat it. I was sick and had to leave off eating.

I had a very bad night afterwards. A horrible nightmare haunted me. Every time I dropped off to sleep it would seem as though a live goat were bleating inside me, and I would jump up full of remorse. But then I would remind myself that meat-eating was a duty, and so become more cheerful. (Gandhi, *An Autobiography* 1940, Part I, Sections 6 and 7)

Gandhi eventually overcame his reluctance (and apparently his compassion for goats) and began to enjoy eating meat. This went on for a year. But eventually he was overcome with guilt and concluded that lying to his parents was worse than not eating meat. He decided that as long as they were alive, meat eating was out of the question.

In 1888 Gandhi left for England to study law. Before leaving, his mother made him swear a vow administered by a Jain monk that he would never touch meat, alcohol, or women. Initially he subsisted on a diet of boiled vegetables and bread until he discovered a vegetarian restaurant in London. Here he bought a copy of the book *A Plea for Vegetarianism* by the British reformer Henry S. Salt (1851–1939), one of the first advocates of animals’ rights. The book discussed the moral reasons for being a vegetarian, including the inherent violence in the eating of meat and the

nonviolence that could be achieved from abstaining from it – ideas that Gandhi could identify with the Indian concept of *ahimsa*. This led to another conversion. Rather than abstaining from meat because of his vow to his mother, he did so now from moral conviction “The choice was now made in favor of vegetarianism, the spread of which henceforward became my mission,” he wrote. Gandhi joined the London Vegetarian Society and became a member of the Executive Committee.

Gandhi argued that remaining a staunch vegetarian requires a moral justification and cannot be done only to improve one's health. “Man was not born a carnivorous animal but born to live on the fruits and herbs that the earth grows,” he declared. However, those who became vegetarians purely for health reasons largely fall back. Some vegetarians make food a fetish and think that by becoming vegetarians they can eat as much lentils, beans, and cheese as they liked, although this did not necessarily make them healthy.

Gandhi was not a vegan and always regretted his inability to give up milk, a failing he called “the tragedy of my life.” In his book *Key to Health*, a summary of his views on diet and health written in the early 1940s, he traces his milk drinking back to a serious case of dysentery in 1917. He had not drunk milk for 6 years, so when a doctor friend suggested he should consume milk to build up his strength, he initially resisted. However, the friend pointed out that at the time of taking the vow he had in mind only cow and buffalo milk, so that goat milk was permitted. Gandhi eventually yielded while conceding that he was keeping only the letter, not the spirit, of his vow. But drinking the goat milk immediately restored his health. As a result, he recognized the need to add milk to a vegetarian diet to provide protein, although with certain reservations (mainly because of the danger of drinking the milk of diseased cattle). He also accepted the consumption of unfertilized eggs which do not entail the destruction of life.

While Gandhi rigorously followed his own prescriptions, he was not dogmatic about imposing them on others. He notes that prolonged experimentation and observation convinced him

that there is no fixed rule for all constitutions. And while vegetarianism, which he called “one of the priceless gifts of Hinduism,” is highly desirable, it is not an end in itself. “Many a man eating meat and with everybody but living in the fear of God is nearer his freedom than a man religiously abstaining from meat and other things, but blaspheming God in every one of his acts,” he wrote in his publication *Young India* (Gandhi, *Moral Basis of Vegetarianism* 1999).

Despite his affinity and close ties with the Jains, he did not hesitate to kill insects or have snakes killed if they invaded his ashram, nor did he find it necessary to avoid eggplants or potatoes, as the Jains did. If one does follow these practices, he held that it should not be in a spirit of self-righteousness. Ahimsa is not a matter of mere diet; it is the self-denial and self-restraint behind it that matters.

Gandhi's beliefs about food, while stimulated by his encounter with Western vegetarianism, were deeply rooted in ancient Indian traditions. But whether they had any lasting effect on Indian dietary habits is problematic. Seven months before his assassination in 1948, he declared, “Everybody is eager to garland my photos and statues, but nobody wants to follow my advice.”

Although today India has the world's largest vegetarian population, vegetarians are far from a majority. A 2006 survey of nearly 15,000 people in 19 Indian states found that only 31% of Indians eat no meat, another 9% eat eggs, while 60% eat meat on occasion (Yadav and Kaur 2006). A mere 21% of households consist only of vegetarian members. The proportion of vegetarians is somewhat higher among women than men (34% vs. 28%) and people over the age of 55 (37% vs. 29%). Growing affluence has led to a rise in consumption of animal products in India, as it has done in other parts of the world, and vegetarianism is still strongly correlated with caste: according to the survey, a majority of Brahmins – 55% nationwide and higher proportions in southern and western India. Very few Indians are vegans.

Nonetheless, the ideal of vegetarianism as an ethical choice remains an ideal in Indian society, and India has given the world one of the great vegetarian cuisines.

Summary

Hinduism is the world's third largest religion, but unlike Islam or Christianity, it has no founder, credo, or scriptures recognized by all adherents. Still, certain attitudes and practices are shared by many Hindus, especially related to food. The concept of ahimsa, or noninjury to all forms of life, emerged in the sixth century BCE, and avoiding meat, especially beef, became a dietary ideal. Vegetarianism was also one of the cornerstones of the teaching of Mahatma Gandhi. Although today India has the world's largest populations of vegetarians, only about a third are strict vegetarians, with considerable variations by region and caste. This article surveys the historical ideas associated with Hinduism, especially attitudes towards animals and meat, the transformation of these ideas under the influence of Buddhism and Jainism, the teachings and influence of Mahatma Gandhi, and the status of vegetarianism in modern India.

The greatness of a nation and its moral progress can be measured by the way in which its animals are treated. Mohandas K. Gandhi.

Introduction

Home food gardening is a potential food provisioning strategy that involves utilizing the physical, social, and economic resources of a household to produce food, particularly vegetables, fruits, berries, and herbs. While the division between farming and home food gardening can be blurred, in contrast to farming, home food gardens are in close proximity to the place of residence and involve smaller plots of land as well as a wider diversity of crops (FAO 2004).

Practically speaking, home food gardening has been practiced as a food provisioning strategy for thousands of years (FAO 2004). In the case of the United States (and its earlier status as a British colony), the practice and prevalence of home food gardening has evolved over time. During the early settlement of the United States, cultivating food was a widely adopted practice necessary for survival. However, innovation and then the gradual industrialization of farming and food production enabled a smaller number of farmers to meet the food needs of an increasingly urban non-farming, non-gardening population (Schupp and Sharp 2012). In fact, home gardening for many increasingly became a hobby and a form of leisure rather than a survival strategy (Schupp and Sharp 2012). Thus, over the last two centuries, the decision to engage in home food gardening and the reasons for doing so have evolved and changed, often according to geographic location and

socioeconomic status. For example, in the nineteenth century lower-income households and those living in newly settled lands continued to rely on home gardening as a survival strategy, while the existence of a home garden in more developed parts of the United States became a status symbol for growing exotic foods among the highest classes. As the urban population surpassed the rural population at the beginning of the twentieth century, the practice of home food gardening further declined as the working classes were able to effectively work for wage labor and purchase needed farm inputs from an increasingly productive farming system.

Two important deviations from the pattern of declining home gardening occurred during both World Wars as “war gardens” and “victory gardens” served as “symbolic expressions of patriotism” as well as important sources of food for the country that needed to dedicate substantial industrial resources to the war efforts (Schupp and Sharp 2012). It is interesting to note that during these time periods, the government played a key role in providing educational information to support the resurgence of gardening as gardening skills had diminished among the increasingly urban society of the United States.

At the start of the twenty-first century, there appears to be a resurgence in the practice of home gardening, in part as a result of increasing concerns with the safety and quality of a progressively more industrialized and globalized agriculture and food system, as well as growing economic hardship associated with the Great Recession (NGA 2009). The United States government, as well as nongovernmental organizations, are once again playing a key role in providing support to overcome lack of knowledge and cultural limitations related to home food gardening. Home food gardening is also being actively promoted as an international development strategy in order to improve nutrition and food access in developing nation-states. Important ethical issues, however, arise from social, economic, cultural, and other barriers that exist that limit the ability of home gardens to fully develop as an effective food provisioning strategy.

Prevalence of Home Food Gardening

Despite the decline of home gardening as a primary food provisioning strategy, there remains a substantial number of home gardeners in the United States. The National Gardening Association (NGA) has estimated that nearly 31%, or approximately 36 million households, in the United States engaged in home food gardening in 2008, with even greater participation predicted in the future (NGA 2009). In a statewide survey of Ohioans, 47.6% of households reported engaging in fruit and vegetable gardening in 2008 (Schupp and Sharp 2012). Research has found that contemporary home food gardeners are more likely to be women, be over the age of 45, have incomes greater than \$50,000, be married, and not have children living at home (NGA 2009). In addition, living in the countryside, on a farm, and in a freestanding house all increase the likelihood of a household engaging in home food gardening (Schupp and Sharp 2012). A household experiencing economic hardship also has been found to increase the likelihood of having a home garden (NGA 2009).

Although there is little research documenting the prevalence of home food gardening internationally, it is a practice that has been important in many international contexts. The ongoing pace of urbanization around the globe is likely to impact the character of home gardening in the international context now and in the future. While home food gardening has historically been a food security strategy utilized primarily in rural areas, gardening has become an increasingly significant activity in urban environments (Foeken 2006), particularly as rural populations with agricultural backgrounds move into cities. In urban contexts, home gardening can take a diversity of forms, including gardening in containers or on rooftops.

Benefits of Home Food Gardening

Home food gardening offers a number of potential economic and noneconomic benefits. These include a way for households to address economic hardship, a strategy for households and communities to

improve the nutrition and well-being of residents, a tool for international development, a way for consumers to address environmental and social concerns with the agriculture and food system, and a strategy to increase community food security and sustainability. Moreover, home food gardening has long been used as a survival strategy. The recent rise in home food gardening has been linked in part to increasing economic hardship in the United States during the recession between 2007 and 2009 (NGA 2009). Households can enjoy fresh, local produce while saving money on food bills. Home food gardening not only is a potential strategy to provision food more frugally but also can be used as a source of income generation, particularly through the informal economy. For example, in Toronto, home gardens have become sources of produce for Community Supported Agriculture (CSA) projects, acting as a tool for economic development in the inner city (Patel and MacRae 2012).

Home food gardening is promoted by a number of governmental and nongovernmental organizations as a nutrition and community development strategy, particularly for nations with low levels of development and high levels of poverty and food insecurity. The food insecure can experience increased direct access to food by engaging in home gardening, which can act as an important supplement to field crops, providing a diversity of vitamin and energy rich vegetables and fruits (Marsh 1998; FAO 2004). Research suggests that even small mixed vegetable garden plots can provide a considerable amount of daily recommended nutrients. Home food gardening is viewed as a more sustainable strategy for improving food security compared to other forms of food aid or nutrition supplementation. Moreover, home food gardening can enable households to consume culturally appropriate food while reducing the necessity of relying upon food aid. In addition to providing nutrition, gardening can be an important source of income for poor households in less developed nations (Marsh 1998). Further, home food gardening can help alleviate seasonal food shortages and can provide environmental benefits by minimizing problems like dust and erosion, recycling water, and increasing local biodiversity (FAO 2004).

Gardening has the potential to increase food security at the individual or household level in more developed nations like the United States, as well as to increase food security and sustainability at the community level. Using high-yield, bio-intensive methods, home food gardens can produce a significant amount of food for urban communities (Colasanti and Hamm 2010). A potential form of civic agriculture, gardening can be a type of food production that encourages social and economic development, improving community well-being (Black 2010).

Other human health concerns with the agriculture and food system can be addressed through home gardening in more developed nations. Home gardening enables consumers to act reflexively and practice control in the agriculture and food system by reducing chemical inputs, the use of genetically engineered (GE) crops, or food additives. Home food gardening can serve as a form of moderate physical exercise (Carter 2010). There are therapeutic advantages to engaging in home food gardening, and it can enable individuals to reclaim personal power and demonstrate agency and self-sufficiency (Carter 2010; Black 2010). Further, there are cultural benefits to home gardening (Black 2010). For example, home food gardening can enable immigrants with cultivation backgrounds to engage in practices they are skilled in and produce culturally appropriate foods (Rein and Ross 2009).

Because home gardening is small-scale, it is viewed by some as an environmentally friendly alternative to large-scale, globalized conventional agriculture and food production. Home gardening allows consumers to have greater control over production, processing, and distribution practices. By minimizing application of chemical inputs, home food gardeners can engage in practices that are potentially better for soil, air, and water quality. By planting a diverse assortment of crops, home food gardening can be an effective way to increase biodiversity conservation (Webb and Kabir 2009). For example, home food gardeners can utilize heirloom seed varieties, ensuring the maintenance of biodiversity in agricultural crops. Home food gardeners can help mitigate biological extinctions that may occur with climate change by

consciously using native plants in their garden designs (Van der Veken et al. 2008). Reduction of the food miles involved in agricultural production can be accomplished through home food gardening, limiting the ecological footprint of food production. In fact, home gardens create the shortest possible distance between producers and consumers (Mariola 2008).

Limitations to Home Food Gardening

Potential barriers can limit the full achievement of the many positive aspects of home food gardening. For example, while home food gardening can improve ecological conditions in the agriculture and food system, people engaging in home food gardening do not necessarily employ more ecologically sound food production practices (Hinrichs 2003). Home gardening does not correct social problems with the agriculture and food system, particularly issues related to improved food access. Engaging in home gardening requires resources, including time, knowledge, space, and money, as well as motivation and interest. A lack of resources for or interest in home gardening can act as potential barriers to participation in this activity.

While not fully discounting the potential benefits of home gardening, there are demographic factors which could influence the ways in which households experience these barriers, including race and ethnicity, social economic status, as well as geography. For example, socioeconomic status (SES) can act as a barrier to local food system participation. Research suggests that people of lower SES are disproportionately underrepresented in alternative agriculture and food movement activities (Hinrichs 2003), such as gardening. One reason for this might be that low SES households do not have access to resources, especially monetary resources, which are necessary for the purchase of equipment and supplies needed to set up and maintain a garden. The time available for participation in home gardening might be affected by SES. Higher SES households are more likely to experience time constraints based on family or household responsibilities,

which are considered more flexible, while lower SES households are more likely to experience time constraints based on work responsibilities, which are less flexible (Inglis et al. 2005). Thus, in relation to time, home gardening is more challenging for lower SES households. It has been asserted that the local foods movement promotes middle and upper-middle class values and promotes certain types of foods traditionally consumed by middle and upper middle class households (Guthman 2011). Marking lower SES households as outsiders can influence the degree of interest lower-income households have in home gardening and thus their motivation to participate in this activity. Knowledge can be a further potential barrier, given that gardening requires specialized knowledge about subjects such as soil health, the timing of planting, pest management, and harvesting. Informal social networks as well as access to other resources, such as university extension information, can play a key role in providing lay knowledge about how to produce and prepare food (Fonte 2008). This knowledge is not accessible to all equally, with those of lower SES being more likely to report lack of knowledge as a barrier to engaging in home food gardening.

Race and ethnicity can act as a barrier to home food gardening. Inequalities based on race and ethnicity, which are historically embedded in local communities, can be reproduced in alternative agriculture activities, such as gardening, excluding non-white participants (Guthman 2011). Priorities about what and how to eat established by white participants of alternative agriculture and food movements do not necessarily match the preferences or priorities of non-white households (Guthman 2011). As home gardening comes to be defined as an activity for white people, minorities potentially have less interest in or motivation to participate. Race and ethnicity could interact with other barriers, including knowledge, time, space, and money, in so far as racial and ethnic inequalities intersect with social class inequalities. This limits the potential of home food gardening to act as a tool for increasing food security and food sovereignty.

Issues of space and place affect the decision to participate in home food gardening. People living

in the countryside, on farms, or in freestanding houses are more likely to participate in home food gardening because they are more likely to have access to the vital resource of space (Schupp and Sharp 2012). Urban agriculture, a potential form of home gardening, is becoming an increasingly popular activity, with cultivation occurring in diverse spaces, including containers, abandoned properties, and public parks. Nevertheless, those living closer to urban centers likely have less space, especially if they reside in multi-dwelling housing units, condos, or apartments, making them more likely to have to confront the obvious challenge of where to garden. These physical factors can interact with race/ethnicity and socioeconomic status. For example, higher incomes enable people to live in a freestanding home, and to own that home, which allows them greater freedom to install and maintain a home garden. For some living in urban areas, the line between private and public property becomes blurred, and individuals will often squat on urban land in order to engage in home food gardening (Rein and Ross 2009). The growth of the community gardening movement is helping pave the way for legal changes in order to expand urban gardening (Hamilton 2011), increasingly allowing gardening on previously abandoned properties. However, as blighted urban properties improve through the efforts of local gardeners, these properties can become attractive for residential or commercial redevelopment (Rein and Ross 2009). Further, social networks have been found to be important in motivating and supporting the practice of gardening (Schupp and Sharp 2012). Therefore, not living in a community which engages in or supports home food gardening can act as a barrier to participation.

The potential benefits of home gardening may be offset by the increased physical and psychological burden of this work, which often falls to women. Internationally, women remain responsible for many aspects of providing food for the household, suggesting that women disproportionately have responsibility for home food gardening. Research suggests that women are more likely to garden for household food provisioning and are more likely to engage in

ecologically beneficial production practices (Reyes-Garcia et al. 2010). Women remain predominantly responsible for preparing and serving food for the household. Therefore, the additional labor involved not only in growing food in home gardens but also processing that food for household consumption adds to women's labor. This additional work can add stress and hardship to women's lives.

There are limitations to home food gardening as a tool for international development. While often viewed as a panacea for food insecurity in less developed countries, for households to engage in home food gardening, they must have access to land, water, seeds, and technical assistance. Thus, home food gardening as an international development strategy is not always as cost-effective as other nutrition intervention strategies. Moreover, development projects promoted by international nongovernmental and governmental organizations utilizing home food gardening are often poorly designed, are poorly managed and monitored, and lack sustainability (Marsh 1998). In addition, the use of gardening as a tool for development is limited by land grabbing. Increasing concern about global climate change is leading to the acquisition of land in developing countries which has previously been used for household food cultivation by the food insecure. Increasing urbanization in developing nations also limits the ability of gardening to act as a tool for increased food security.

Summary

Home food gardening is a longstanding, but evolving food provisioning strategy that provides opportunities for improving social, environmental, and human health outcomes of the food and agriculture system. Yet a number of challenges remain that limit the full achievement of these potential benefits. Sociodemographic factors such as social class, race/ethnicity, gender, and geography all influence the degree to which home food gardening can be a viable strategy for improved agriculture and food system health and well-being. Nevertheless, there are a number of

development opportunities which can help mitigate the barriers to home gardening, enabling the potential benefits of home gardening to flourish. Governmental and nonprofit organizations are working to improve access to the resources necessary to engage in gardening. Growing Gardens in Portland, Oregon, Denver Urban Gardens in Denver, Colorado, and the USDA's The People's Garden are all examples of organizations which are building and installing gardens in communities, often for low income households. These organizations provide technical expertise, networking, gardening materials such as seeds and transplants, secure land, and are working to create policy change in order to make gardening a more accessible activity for all. Such activities provide the support necessary to make home gardening a successful strategy for improving social, environmental, and human health and well-being both domestically and globally.

Homesteading

Jessica E. Logue

University of Portland, Portland, OR, USA

Synonyms

Back to the land movement; Self-sufficiency; Simplicity; Sustainable living

Introduction

Homesteading originally refers to the Homesteading Act of 1862 which provided public land grants of 160 acres to any adult citizen who paid a small registration fee and agreed to live on the land continuously for 5 years, after which they would be granted a deed to the land. The program formally ended in 1976 under the Federal Land Policy and Management Act. But its unofficial end was in 1935 when President Franklin Roosevelt withdrew the public domain lands in order to institute a nationwide land conservation program. During the life of the Homestead Act, 783,000 men and women ‘proved up’ their claim and were granted title to the land (Hunt 2007).

In the 1970s the term “homesteading” became synonymous with self-sufficiency, and since then homesteading has come to be seen as a self-sufficient mode of life where individuals attempt to provide for themselves by growing, raising, and preserving their own food, making cleaning supplies, in some cases providing their own sources of energy, and living completely off the grid. This movement is heavily linked to the “back to the land movement” of the 1970s which was characterized by Thoreauvian simplicity, environmental awareness, and the rejection of consumerism. Modern homesteading embraces not just self-sufficiency but also sustainability.

Major Players in the Homesteading Movement

John Seymour published *The Self-Sufficient Life and How to Live it* in 1976. The book is a guide to

gardening, animal husbandry, hunting wild, foraging, cooking and preserving, self-sufficient energy, and other skills like basketry, carpentry, woodworking, etc. Seymour was born in London in 1914 and was a writer, environmentalist, and activist until his death in 2004. Seymour promoted a simple and self-sufficient lifestyle and denounced consumerism, genetically modified organisms, and automobiles while advocating personal responsibility and self-sufficiency as well as care for the soil. Seymour himself wrote of his treatise in 2003, “Since [writing] the first edition of this book back in 1975 . . . there is a far more urgent reason for it. Very few people today can fail to see that the present course that man – and woman-kind is embarked upon is unsustainable” (Seymour 2003).

The Storey Publishing Company has offered similar volumes about aspects of homesteading, like raising chickens, beekeeping, rug making, log home building, gardening, knitting, candlemaking, composting, etc. They have been publishing these volumes since 1983, claiming that Storey is at the center of a vast revival of do-it-yourself lifestyles, a movement that has been fueled by an awareness of environmental responsibility, an appetite for the homegrown and locally raised, an appreciation for one-of-a-kind items, and a passion for nature. Whether picking up a needle and thread for the first time, or nurturing a decades-old passion for horses, readers know that they can turn to Storey for no-nonsense advice and new ideas – every time (Storey Website 2012).

The company hires experts to write these guides and have the goal of “provid[ing] dependable, nuts-and-bolts advice to spirited readers seeking to become more self-sufficient” (Storey website 2012). The company was founded by John and Martha Storey, a couple from Charlotte, Vermont, who bought the Garden Way imprint in 1983 and first published Dick Raymond’s classic volume *The Joy of Gardening*. Storey Publishing has “sold over 35 million volumes and has more than 400 active titles, 70 of which have sold more than 100,000 copies” (Storey Website 2012). Storey published *The Backyard Homestead* by Carleen Madigan in 2009. That particular volume

shows that you can produce a wealth of your own food on one-quarter of an acre of land. That wealth of food includes 50 lb of wheat, 280 lb of pork, 120 cartons of eggs, 100 lb of honey, 25–75 lb of nuts, 600 lb of fruit, and more than 2000 lb of vegetables (Madigan 2009).

Kelly Coyne and Erik Knutzen published *The Urban Homestead* in 2010. *The Urban Homestead* serves as a treatise for just that. Coyne and Knutzen illustrate that one can become more self-sufficient through rather simple means and still live in a metropolitan area. Coyne and Knutzen are a married couple living in Los Angeles. Their book shows ways to grow vegetables in small spaces, compost, forage in urban areas, raise animals on a city lot, provide your own power, and make and preserve many of your own foods and cleaning products. Coyne and Knutzen describe their project as a shift “from being consumers to being **producers**.” They still “buy stuff. Olive oil. Parmigiano reggiano. Wine. Flour. Chocolate” and are “no strangers to consumer culture, not above experiencing a little shiver of desire when walking into an Apple computer store” (Coyne and Knutzen 2010).

Why Self-Sufficiency Has Become a Concern

Self-sufficiency has become a concern for many in the face of (1) dependence on foreign oil, (2) food-borne illnesses, (3) regaining lost skills like canning and preserving, and (4) environmental concerns.

Dependence on Foreign Oil Modern society is heavily dependent on oil as a source of fuel. Cars run on oil. Homes are heated by oil. Oil is used to make a variety of products that are used on a daily basis. Many countries rely significantly on foreign sources of oil. There is also considerable uncertainty concerning how much oil is under the surface of the earth and how long that supply will last. If the supply suddenly runs out, the impact on the food system is undeniable. “After cars, the food system uses more fossil fuel than any other

sector of the economy – 19 %. And while the experts disagree about the exact amount, the way [people feed themselves] contributes more greenhouse gases to the atmosphere than anything else [they] do – as much as 37 %, according to one study” (Pollan 2008). Additionally, Michael Pollan claims that dependence on foreign oil sources has made citizens in the United States more vulnerable, “For nations that lose the ability to substantially feed themselves will find themselves as gravely compromised in their international dealings as nations that depend on foreign sources of oil presently do. But while there are alternatives to oil, there are no alternatives to food” (Pollan 2008).

Food-Borne Illnesses Food-borne illnesses have been a growing problem with the centralizing of American food production. The Center for Disease Control’s most recent statistics about food-borne illnesses are from 2011 and they “estimate that each year roughly 1 in 6 Americans (or 48 million people) gets sick, 128,000 are hospitalized, and 3,000 die of foodborne diseases” (CDC website 2012). The CDC currently divides food-borne illnesses into two categories: known food-borne pathogens (which includes 31 different pathogens that are known to cause illnesses) and unspecified agents (which includes chemicals, known agents that have not been proven to cause illness, agents that have not been identified, and other substances “whose ability to cause illness is unproven”). The top 5 pathogens that cause the most illnesses in the United States are norovirus, salmonella, *Clostridium perfringens*, *Campylobacter* spp., and *Staphylococcus aureus* (CDC website 2012).

Regaining Lost Skills Many writers and food activists have commented about lost domestic skills. Since the time of the Industrial Revolution, households have relied upon men working away from the home, and as this increased, the household’s demand for products made outside of the home increased (Hayes 2010). As the household shifted from being a unit of production to a unit of consumption, many of the traditional skills had by housewives have been lost. Skills like gardening,

canning and preserving, cheese making, sewing, and even carpentry and repair work around the home have been outsourced to industrialization. As Shannon Hayes notes, “The industrial revolution brought changes to the family hearth as well” (Hayes 2010). Industrialization provided commodities like stoves and shoes, but in order to afford these things, men needed to work outside the home. And the more time outside the home led to men being freed of household tasks but also led to the need for a consumer economy in which the man of the family “needed to know...how to make salable product[s] or keep a job to pay cash for his family’s necessities” (Hayes 2010). Factory work provided cash to buy commodities rather than make them. Some commodities (like electricity) eliminated the need for others (like candles), and others, like home-canned food, were exchanged for store-bought similar products. According to homesteading philosophy, the path to a simpler life, one freer from consumerism and dependency, includes regaining these lost skills.

Environmental Concerns Many of these concerns are linked to a dependence on foreign oil, but there are also growing concerns about other environmental impacts of an industrialized and centralized food culture. Factory farms, or CAFOs (Concentrated Animal Feeding Operations), bear the brunt of much scrutiny over their environmental impact. As Michael Pollan claims, “if taking the animals off farms made a certain kind of economic sense, it made no ecological sense whatever: their waste, formerly regarded as a precious source of fertility on the farm, became a pollutant – factory farms are now one of America’s biggest sources of pollution” (Pollan 2008). CAFOs create a lot of waste; animals kept in confinement create a lot of waste that creates a lot of pollution. Additionally, the inefficiency of raising animals fed on grain creates more waste.

The Ethics of Self-Sufficiency

Proponents of homesteading argue that they are able to save energy, minimize transportation costs (and therefore minimize oil use and reduce carbon emissions), provide healthy home-cooked foods

for themselves and their families, and create a home atmosphere that is not based on consumerism (Seymour 2003). Dependence on foreign sources of energy is eliminated if one creates it oneself through the use of solar panels, wind turbines, etc. Activists like Seymour claim that these actions benefit the commons and thwart the effects of the tragedy of the commons. For instance, if people are able to reduce their own pollution through energy conservation and alternative methods, then they will promote the reduction of pollutants overall and promote clean air, water, and soil (Seymour 2003). Similarly, if they are able to reduce their transportation costs by walking and cycling more, then the same purposes of promoting less pollution are served. Additionally, if citizens are not reliant on getting their food from other distant places, then they will reduce the amount of oil used to feed themselves and also the amount of pollution in the water, soil, and air. Having more control over what one eats by growing, raising, and producing it oneself, one is better able to have healthier foods but also, in many cases, tastier ones (Seymour 2003).

Critiques of Homesteading

Most concerns about homesteading stem from problems had by suburban and urban dwellers. There are certainly concerns about how feasible it is for a person or family to homestead in the suburbs or urban areas. Growing one's own food on a small patio space or in containers is quite limiting and will not produce enough for one, or one's family, to become self-sufficient. Additionally, many cities have ordinances forbidding homeowners from activities like beekeeping or raising chickens, which limits the amount of food one can produce for oneself.

Homeowners in the suburbs or urban areas may also face concerns from neighbors over the unsightliness of, for instance, having a wind turbine in one's backyard; utilizing a material like bubble wrap on one's windows during the winter, as some homesteaders do (Coyne and Knutzen 2010); or growing a vegetable garden in one's front lawn instead of having a usual, grass-

covered front lawn. Neighbors may fear that their own homes will lose property value by being next door to or in the same vicinity as homesteaders. Coyne and Knutzen offer some troubleshooting on this matter, suggesting that if one wants to do away with one's front lawn, then the subsequent garden must be a "show piece" to avoid consternation from neighbors (Coyne and Knutzen 2010).

Although the feasibility of homesteading in the suburbs or urban areas is a concern, there are still many measures an individual or family can take. One can grow some herbs or produce in containers. Fruit trees also can be grown up against fences or walls (Coyne and Knutzen 2010; Seymour 2003). If all else fails, many suburbs and cities offer community gardens where participants can secure a plot of land to plant fruits and vegetables.

Summary

Homesteading is not for everyone. It is difficult and requires a lot of planning, time, and commitment, as well as land (in many cases). However, with concerns about the use of oil, food-borne illnesses, and dependency on others to create most of what is consumed, it is an alternative to consumerism and reliance upon others for one's food.

Introduction

Horticultural therapy is the practice of using horticultural activities for human healing and rehabilitation. Reference to the healing power of gardens and nature can be found as far back as ancient Greek times and through to recent times. In the United States, earliest articles published regarding the value of horticulture and gardening to human health are from the 1800s.

This entry will present the historical background of the profession of horticultural therapy in the United States, mention the key people in

establishing the profession, define horticultural therapy, review the theoretical framework, and consider the future of the profession.

History

Treatment, rehabilitation, and/or residential care of individuals with disabilities during the 1800s up to around the 1950s often relied on agriculture as a major part of the facility. However, the farm was important for providing food to the facility and work on the farm was not intended as treatment but rather as a way for those individuals who could not pay to be at the facility to earn their room and board. It was the observation that those individuals who were required to work actually progressed toward return to the community faster that led to the recognition that staying occupied with responsibilities actually expedited rehabilitation. This in turn led to the development of occupational therapy and all subsequent allied activity therapies.

Dr. Benjamin Rush, a professor of the Institute of Medicine and Clinical Practice at the University of Pennsylvania and considered to be the father of American psychiatry, wrote in his book *Medical Inquiries and Observations Upon Diseases of the Mind* published in 1812 that “Man was made to be active. Even in paradise he was employed in the healthy and pleasant exercises of cultivating a garden” and that “agriculture by agitating the passions by alternate hope, fear, and enjoyment, and by rendering bodily exercise and labour necessary, is calculated to produce the greatest benefit” (Rush 1812). From its opening in 1813, patients at the Friends Asylum for the Insane in Philadelphia, Pennsylvania, worked in the vegetable gardens and fruit tree plantings. When Pontiac State Hospital in Michigan opened on 300 acres, it made extensive use of farming and dairy projects. However, production was the chief goal, and any therapy these patients received was a fortunate by-product. Dr. Thomas Kirkbride, superintendent of the Pennsylvania Hospital for the Insane and founder of the American Psychiatric Association, encouraged patients to work in the gardens or shops to aid recovery in his book

On the Construction, Organization, and General Arrangements of Hospitals for the Insane with Some Remarks on Insanity and Its Treatment (Kirkbride 1854).

The earliest articles published in the United States indicate a broad view of benefits to be gained from gardening from helping mental patients to easing the stressful lives of the urban poor and as an aid in teaching mentally handicapped individuals. In *Darkness and Daylight or Lights and Shadows of New York Life* (Campbell et al. 1895), the impact of flowers on the poor, the infirm, and prisoners is described. In the *Journal of Psycho-Aesthetics*, E.R. Johnston (1899) writes: "In the garden every sense is alert. How the eye brightens at the masses of gorgeous color and the beautiful outlines – how many things, hot and cool, rough and smooth, hard and soft, and of different forms are to be grasped and held by trembling uncertain hands whose sense of touch is hardly yet awakened."

In the United States, the significant growth of occupational therapy (OT) programs in Veteran Hospitals at the conclusion of World War II was really the impetus for the beginnings of the profession of horticultural therapy. Between 1920 and 1940, most books on OT mentioned gardening (Sullivan 1979). In 1936, the Association of Occupational Therapists in England formally acknowledged the use of horticulture as a specific treatment for physical and psychiatric disorders (McDonald 1995). Milwaukee Downer College, the first college to award a degree in occupational therapy, was also the first institution of higher learning to offer a course in horticulture within the occupational therapy curriculum, in 1942. After 1940, garden therapy was considered a separate treatment, and the first use of the term horticultural therapy was used by Ruth Mosher Place in 1948 (Olszowy 1978).

In 1952, the first weeklong workshop in horticultural therapy was offered at Michigan State University by Dr. Donald Watson and Alice Burlingame, a psychiatric social worker. This followed with the first master's degree program in horticultural therapy for occupational therapists. The first Master of Science degree in horticultural therapy was awarded by Michigan State

University to Genevieve Jones, an occupational therapist, in 1955. The first book in horticultural therapy, *Therapy through Horticulture* by Burlingame and Watson, was published in 1960 (Burlingame and Watson 1960). Working under Dr. Karl Menninger from 1946 to 1953 at the Menninger Clinic, Topeka, Kansas, Rhea McCandliss became one of the first professional horticultural therapists.

The next significant steps occurred in the early 1970s with the establishment of university programs and creation of a professional association. In 1972, Kansas State University, with the cooperation of the Menninger Foundation in Topeka, Kansas, began an undergraduate curriculum in horticultural therapy (Odom 1973). Several other universities followed suit. The University of Maryland awarded a Master of Science in Horticulture for work by P.D. Relf in Horticultural Therapy in 1972 and PhD in 1976. In 1973, Clemson University offered a graduate degree in horticultural therapy (HT) and Michigan State University started its undergraduate horticultural therapy option in horticulture, which included 12 weeks of practical training at the Clinton Valley Center, formerly Pontiac State Hospital.

In 1973, the National Council for Therapy and Rehabilitation through Horticulture was formed to promote and enhance the profession as a therapeutic intervention and rehabilitative medium. It became the American Horticultural Therapy Association (AHTA) in 1987. Annual conferences began in 1973. Professional registration was established by the AHTA in 1975 based on a peer group review of qualifications. In 1985, the AHTA approved a core curriculum largely modeled after the Kansas State University curriculum. The *Journal of Therapeutic Horticulture*, the professional publication of AHTA, has been produced since 1986.

Volunteers have also had an important role in the development of horticultural therapy. Volunteers and members of the National Council of State Garden Clubs assisted occupational therapists in using plants and gardening activities in their therapy and rehabilitation programming, particularly following World War II. In 1951, the National Council of State Garden Clubs named

horticultural therapy as one of the major objectives of member clubs, which it remains today (Simson and Straus 1998). Master Gardeners, another group of volunteers, are university-trained and serve as educators in their communities with primary emphasis on home gardeners. When the Master Gardener program began in the mid-1970s, its focus was primarily directed at diagnosing plant problems and offering solutions. While still a major focus, Master Gardeners now assist in a variety of educational programs including programs regarding the welfare of the youth, senior citizens, and persons with disabilities. Research on the role and impact Master Gardeners have in horticultural therapy began to be reported in the 1990s (e.g., see Flagler 1992; Kafami 1997; Marshall 1997).

Defining Horticultural Therapy

The definition of horticultural therapy lends itself to either brief discussion or endless debate, depending on who is having the conversation. Definitions range from the simple (plants make people feel better) to the complicated (the use of plants by a trained professional as a medium through which certain clinically defined goals may be met). Given this broad spectrum, several other terms have been proposed in an effort to make distinctions along the spectrum, with limited success. For example, some agencies and associations use therapeutic horticulture to distinguish between programs with a predefined clinical goal (horticultural therapy) and those directed toward improving well-being in a more generalized way (therapeutic horticulture). Other examples are social horticulture and horticulture well-being. Unfortunately, these terms (and many more) are often used interchangeably so rather than aiding in defining the profession it has fostered confusion.

The following definitions are from primary sources for the profession of horticultural therapy today.

While there are a growing number of print publications on horticultural therapy, there are a limited number of university-level textbooks on the subject. The definition from *Horticulture as*

Therapy: Principles and Practice (Simson and Straus 1998) is:

Horticultural therapy is a process through which plants, gardening activities, and the innate closeness we all feel toward nature are used as vehicles in professionally conducted programs of therapy and rehabilitation.

The American Horticultural Therapy Association (AHTA) is the only national organization for the promotion and development of HT programming in the United States. The definition from AHTA is (www.ahta.org):

Horticultural therapy is the engagement of a person in gardening-related activities, facilitated by a trained therapist, to achieve specific treatment goals.

Dr. Diane Relf, professor emeritus at Virginia Tech University, was one of the founding members of AHTA and spent her career defining and promoting the practice of HT through her research and work. Her definition is (Relf and Dorn 1995):

There are four elements that are essential for an activity to qualify as horticultural therapy if it is to be considered a profession eligible for the same status as other caring professions.

- A defined treatment procedure that focuses on horticultural or gardening activities
- A client with a diagnosed problem who is in treatment for that problem
- A treatment goal that can be measured and evaluated
- A qualified professional to deliver the treatment

The Horticultural Therapy Institute is a private, nonprofit organization that provides educational programs in HT. Rebecca Haller is the director and along with Christine Kramer are editors of a book titled *Horticultural Therapy Methods – Making Connections in Health Care, Human Service, and Community Programs* (2006). Their definition of HT is:

Horticultural therapy is a professionally conducted client-centered treatment modality that utilizes horticulture activities to meet specific therapeutic or rehabilitative goals of its participants. The focus is to maximize social, cognitive,

physical and/or psychological function and/or to enhance general health and wellness.

Kansas State University is considered a leader in higher education in horticultural therapy. The following definition is from the K-State Study Guide *Horticultural Therapy* which is a promotional piece provided to perspective students:

Horticultural therapy is a process directed by a horticultural therapist using flowers, fruits, vegetables, and ornamental plants to provide people with social, psychological, physical, and intellectual benefits.

The Chicago Botanic Garden is considered a leader in horticultural therapy program development and delivery as well as education. The definition from CBG is (www.chicagobotanicgarden.org):

Horticultural therapy is the professionally directed use of plant, gardening, and nature activities for the purpose of restoring the physical and mental health of its participants.

A close study of these definitions demonstrates some agreement as well as differences among the leading individuals, associations, and institutions in horticultural therapy.

People-Plant Interaction

The philosophical basis of HT is that all humans have a basic need for contact with nature and that this contact will have a positive influence on them. The biophilia hypothesis, the functional-evolutionary theory, and the psycho-evolutionary theory are often cited to support this philosophy. E.O. Wilson's biophilia hypothesis (Kellert and Wilson 1993) states that humans have an innate relationship with the environment and our responses too and relationship with the environment are biological. Kaplan's functional-evolutionary theory (Kaplan and Kaplan 1989) and Roger Ulrich's psycho-evolutionary theory (1983) further explain the healing influence of environments on human beings. Both hypothesize that restorative environments are settings where recovery is associated with reduction of stress and that the benefits of contact with landscapes include a wide range of positive responses, such as preference, and/or reactions related to

functioning and well-being. Both theories are based on Wilson's evolutionary perspective.

Considerable anecdotal reports and practical experience show the possible benefits of working with plants in many different settings. Research findings and case studies highlight the positive cognitive, social, psychological, and physical outcomes of nature and gardening. Reported benefits include social integration; increased self-confidence, self-esteem, and concentration; improved health; reduced stress and mental fatigue; and learning of practical skills, structure, and routine (for recent reviews, see Sempik et al. 2003; Gezondheidsraad 2004; Elings 2006). While the number of research publications continues to grow, most of the research to date is purely descriptive and contains little, if any, actual quantitative or qualitative data. Little is known about the mechanisms behind HT and evidence is weak due to the methodological limitations of many of the studies. Additionally, many of the studies report on benefits from exposure to nature with non-patient groups rather than active involvement in horticultural activities led by a professional therapist with patient groups. However, there is now sufficient evidence to the efficacy of people-plant interaction for prevention and treatment to justify a serious research effort.

Considerations for the Future

Many allied health therapies, such as recreational therapy, music therapy, and art therapy, emerged following WWII similar to the horticultural therapy profession. While these related allied therapies have been successful in becoming established health professions, horticultural therapy is still referred to as an emerging profession. A comparison of these professions suggests many possible reasons why horticultural therapy lags behind the other professions (Shoemaker 2002). Continued validation and growth of the horticultural therapy profession is critically needed through universal standards for clinical practice; defining and communicating entry level skills and educational attainment; research evidence that can inform the practice of horticultural therapy; and

established collaborations between practitioners, academicians, and research scientists.

Summary

Awareness of the healing power of nature is closely linked to the development of human civilization and agriculture. The profession of horticultural therapy emerged following World War II and is supported by this historical awareness. This entry has provided a brief history of the profession, the theoretical framework and definitions for the practice, and the current limitations to the profession.

Hospitality and Food

Raymond Boisvert
Philosophy, Siena College, Loudonville,
NY, USA

Synonyms

Generosity; Entertainment; Liberality; Welcome

Introduction: The Archetypes

Humans need food and shelter. Humans also often find themselves in situations when they must depend on others for that shelter and food. They may be traveling or displaced by emergency, war, and natural disaster. As a result, hospitality, the provision of food and shelter to strangers, is a universal human theme. In the Western tradition, it features as central in two foundational narratives: the *Bible* and Homer's *Odyssey*. Practices and mores from Africa, Asia, pre-Columbian America, and Arab cultures all make of hospitality an honored and prescribed activity. When present, it signals a well-ordered, civilized, properly upright community. When absent, it signals offensive, vulgar behavior. As a focus of attention and prioritization, it tended to be more central in the pre-Modern world. Cultural and intellectual changes altered its meaning and role during the Modern era (1500–1900). Still, it remained a constant point of reference and has occasioned renewed attention in the early twenty-first century.

The code of hospitality's lingering significance was made evident in an early film, Buster Keaton's 1923 comedy *Our Hospitality*. This movie was based on the Hatfield-McCoy feud. A young man, having lived in the city, travels back to reclaim his deceased father's country property. Along the way he falls in love. The young woman brings him home. At that point, her relatives realize that he belongs to the other clan. The family members are honor-bound to kill the enemy. However, as a guest in their home, they are also forbidden from harming him. Since

all restraints disappear once he steps out the door, the entire setting presents a set of quandaries that enhance the comic possibilities. These possibilities make sense only because of a background understanding that goes back deep in time: the obligations associated with hospitality are absolute.

A contemporary Internet search of “hospitality” reveals something quite different. Far from being considered a virtue central to living a good life, the primary context has become an economic one. “Hospitality” now means, first and foremost, the “hospitality industry.” Within this industry, the guest-host relationship is understood as a market exchange. In this way, the early twenty-first century is an exception. Although an economic dimension was always present, even if it involved simply the cost of feeding a guest, that facet tended, in the past, to be more peripheral than central. Archetypal stories from literature offer the major resource for this alternative, more traditional, take on hospitality.

Some stories from the *Bible* and Homer's *Odyssey* provide paradigmatic cases. Whereas the tale of Sodom and Gomorrah has, since the Middle Ages, been understood as an account of sexual license, the main evil is really failing the obligation of hospitality. Lot is the upstanding citizen who offers food and shelter to visitors (actually angels in disguise). The other townspeople deserve punishment because of their failure to properly welcome the strangers. For the *Odyssey*, an important background context involves the chief god Zeus. One of his most important titles is *Zeus Xenios*, Zeus, protector of strangers. Throughout the *Odyssey*, civilized, god-fearing people are easily identified by a key trait: they are hospitable. One model scene involves Menelaus and Helen entertaining Telemachus, the son of Odysseus. Before even asking his name, they welcome him to their home and provide food and shelter. At the other, uncivilized, extreme is Polyphemus, the Cyclops. Rather than greeting his guests by offering food, he first asks their names. Eventually, instead of providing food for them, he makes of them food for himself.

The great archetypal story of hospitality is the tale of Baucis and Philemon. It is found in the

Metamorphoses by the Roman poet Ovid (43bce–18ce). Baucis and Philemon are wife and husband, poor and old. Into their community come two gods, Jupiter and Mercury. Following a common theme, they are disguised as poor beggars. The official word for this is “theoxeny,” a god (theos) pretending to be a stranger (xenos). The villagers mostly slam their doors in the faces of the supplicants, another common theme. Not Baucis and Philemon. They open their door to the guests and hasten to make them feel comfortable, going so far as offering to slaughter their only goose for a meal. The gods, pleased, reward the elderly couple.

Lest anyone think that all hospitality literature is filtered through rose-colored glasses, there are plenty of alternative stories. In addition to the good host/hostess, another paradigm shows up regularly: the bad guest. Outsiders arriving on a doorstep are not always well intentioned. The seventeenth century French playwright Molière seemed especially sensitive to this. Like Keaton, he favored comedies, and like *Our Hospitality*, he built stories around guests. His guests, though, were no innocents. In *Amphitryon* he revives the two guests from Ovid’s story. Only in this case Jupiter comes off as a fully human, randy abuser of his powers. Lusting after a lovely young bride, he develops a sure-fire plan of seduction. Knowing her husband (the *Amphitryon* of the title) is off on military service, he disguises himself as the husband. The unwitting bride welcomes him with open arms.

With his more famous play, *Tartuffe*, Molière does something similar. In this case there are no disguised gods, just a hypocrite who is a good actor. Tartuffe is the kind of guest who does not at all appreciate the kindnesses visited on him. Instead he is scheming to dispossess his host in various ways: plotting to seduce both the host’s wife and daughter and plotting also to take over the owner’s home and belongings.

Hospitality and Ethics

Such stories suggest that when simple questions are asked about hospitality, the answers cannot be

so simple. This is what makes hospitality both attractive and challenging when it comes to ethics. Traditionally, the ethical code associated with hospitality is both strong and rigid. The stranger must be welcomed. Food and shelter must be provided. In practice, there is always both flexibility and wariness. Bedouins, for example, extend the guest’s welcome only through the time (three or so days) that the initial shared food would work its way through the body. The absolute claim of hospitality is tempered by practical considerations.

The Latin term *hostis* indicates another issue, the “Tartuffe” problem. The word *hostis* can mean both enemy and stranger. Will the stranger prove to be friend or foe? The answer is not always evident. Humans often seek an ethics that avoids personal responsibility and an ethics that will provide fixed rules or fixed procedures to follow. Responsibility, by contrast, involves assuming the liability for some individual, context-sensitive response. Hospitality can play an important role in dealing with ethics because, as the ambiguous term *hostis* indicates, an easy, fixed sizing up of a situation is often not the case. Hospitality as a paradigmatic ethical case involves *both* a mandate – welcome the stranger – *and* a caveat: be wary. In the hospitality context, it is hard to avoid some dimension of personal input and judgment when attempting a proper response to surrounding conditions. The case of hospitality is one within which there will always be risks associated with the combination of obligations and uncertainties.

Such complications are reinforced when examining the etymology associated with another Latin word. *Hospes*, like *hostis*, has a double meaning. It could be either “guest” or “host” depending on the context. To be a *hospes* signals first and foremost to be someone participating in a particular relationship. The use of a single, specifically ambiguous term, rather than two clearly separable ones, indicates how it is the relationship that takes priority. “Host” and “guest” are flexible because the roles within the general relationship can, in various circumstances, be inverted.

Hospitality epitomizes the ethical situation because it regularly involves unavoidable tensions.

There is, first of all, the question of whether individuals will accept the traditional mandate of providing hospitality. If the answer is yes, the next issue is how to ensure that this is best put into practice. Then, even if the obligation is assumed, there is the “Bedouin question” regarding the degree and duration of hospitality. There is also the “Tartuffe” question of whether this particular stranger should serve as an exception to the general rule. As a result, hospitality exemplifies three important concerns relating to ethics. First, whatever action is undertaken can be followed by the question “is it good?” This is so even if the action in question obeyed to the letter some ethical dictate. Second, in the lives of complicated creatures like humans, a particular obligation never stands alone. The situation in which humans find themselves may be one in which various goods and virtues conflict. Virtues and duties are always plural. Finally, proper ethical comportment is a thread woven together by combining good sense, prior experience, guiding principles, duties, communal practices, well-developed habits, and practical judgments.

What emerges from such tensions is an important lesson at the intersection of hospitality and ethics. “Casuistry,” now a discredited term, was once honorific. It identified the complicated process appropriate for dealing with complicated situations. At least since the time of René Descartes (1596–1650), philosophers, resisting casuistry with its fuzziness, knotty distinctions, nitpicking details, and multifaceted sensitivity to situation, have sought instead clarity and distinctness. Clarity and distinctness, in turn, require a kind of policing, the kind that often prizes purity and the construction of rigid boundaries. In such a context, strangers should fit the neat category of either friend or foe. Such neat categorizations, though readily available in abstract thought, are less prevalent in concrete life situations. Wherever opposites can perhaps intersect, as with the dual meaning of *hospes*, and wherever evidence for removing uncertainty is imperfect, as with *hostis*, there will be responsibility, risk, and anxiety. Several strands in philosophy, especially strong during the Modern epoch, sought to allay responsibility and anxiety. The hospitality/ethics

connection is important because it provides a paradigmatic case that can never be free of the responsibility/risk/anxiety axis.

In this way the hospitality/ethics intersection, when taken seriously, brings with it certain implications. Some revised version of “casuistry,” difficult thinking about individual cases, has to be undertaken. In addition, two non-algorithmic themes made prominent by the ancient philosopher Aristotle (d. 322) also come to the fore: (a) living a good life involves finding the right middle ground and (b) in seeking such ground it is important to use as models, not fixed formulas, but rather experienced individuals, people with practical wisdom.

The stranger represents a question mark, an initial fuzziness. It is this kind of initial enigma which makes the ethics/responsibility/risk/anxiety chain impossible to avoid. There are always strangers, wanderers, the homeless, and the hungry. One possible response: follow the example of Baucis and Philemon’s neighbors and turn the strangers away. If the visitors turn out to be Tartuffe, then such would be the better decision. Another possible response: follow the example of Baucis and Philemon by opening our doors and sharing our tables? If the stranger is, to draw on another paradigmatic story, Babette, from Isak Dinesen’s *Babette’s Feast*, then electing this option is the more commendable one. It is because hospitality represents a constant and open call for one risky response or another that it intersects necessarily with ethics.

Hospitality: Past and Present

In the pre-Modern world, hospitality was often understood in a wide sense that implicated various areas of human life. For the ancient Greek lawmaker Solon (638–558 bce), the notion of eating together was actually considered an important component of a healthy body politic. Solon prescribed common eating on a rotating basis for citizens. Those who sought constant access to the free meals were derided as moochers and gave rise to the pejorative sense associated with “the one who eats next to us,” the “parasite.” The

opposite behavior, rejecting the state's hospitality, also deserved a reprimand. Those who refused to share in communal meals were accused of failing in public-spiritedness. Not only was accepting the hospitality of the community by eating in the central refectory a regular obligation, Solon's laws themselves were on display there.

The Athenian leader Pericles (495–429 bce) highlighted the importance of hospitality in his famous *funeral oration*. He proclaimed that a sign of Athens' greatness was its openness to strangers, even as he admitted the tension associated with such hospitality: "We throw open our city to the world, and never by alien acts exclude foreigners from any opportunity of learning or observing, although the eyes of an enemy may occasionally profit by our liberality. . . ."

During the Enlightenment, when intellectuals dreamed of a new era marked by continuing progress guided by the light of reason, the approaches to hospitality took a different turn. One of the most fascinating texts of the Enlightenment was the famous eighteenth-century *Encyclopédie*, which, as its name indicates, was an attempt to gather in a multivolume work all the most important knowledge that was available. The *Encyclopédie* continued the ancient tradition of praising hospitality. As a product of its day, it did so with several important twists. The first was to move "hospitality" from a virtue to a duty. The second was to emphasize hospitality, not for itself, but as a vehicle for providing lessons of importance regarding other matters.

Both "virtue" and "duty" are important terms in the discourse of ethics. Both indicate an acknowledgement that comporting oneself in a particular manner is important. They differ in that a virtue has to be woven into one's character. It is a habitual mode of acting, one that plays itself out as a kind of second nature resulting from character development. In other words, the virtuous activity is not felt as an external imposition. A "duty," by contrast, need not be that which emerges comfortably from character. There is recognition of some activity which must be undertaken, but it need not come naturally or habitually. Indeed, there may be recognition of how important it is to do the right thing even if it goes against

habituated inclinations. The *Encyclopédie*, true to its time, tended to identify hospitality with duty. Its entry on "duty" gave as examples "the duties of compassion, of liberality, of beneficence, of recognition, of hospitality. . . ."

When it came to object lessons making use of hospitality, the most important one had to do with a "golden age" attitude toward what was thought to be a more innocent past. For example, the entry "Canadians, Philosophy of" was really about the Hurons. The first impression of the "savages," the article noted, was "unfavorable." However, what eventually becomes evident is how "they are kind and affable, and toward foreigners and unfortunates, *they practice a charitable hospitality that puts all the nations of Europe to shame*" [emphasis added].

The last line indicates the second important change for the understanding of hospitality during the Enlightenment. Not only had it come to be considered a duty, but was to be used as a tool for propagating newer modes of thinking. In the specific case cited, hospitality was employed to mark a distinction between native peoples and Europeans. The former were envisioned as purer, less damaged, and closer to what was thought of as the "state of nature." The latter were represented as more corrupted, artificial, and inauthentic representatives of humanity.

One of the *Encyclopédie*'s main authors, Denis Diderot, also used hospitality in this way. His approach was fictional. It envisioned the contact between a European priest and natives of lands newly discovered by the Europeans. The French priest is made welcome by his Tahitian hosts. It is the content of the welcome that changes the usual pattern of hospitality. Whereas sharing shelter and food is typical, Diderot's Tahitian host has another sharing in mind. As part of the welcome, he offers to the priest, while parading them naked, his daughters. It is not right, the host claims, to spend a night alone. It is also not right that his youngest daughter has yet to become a mother. Such an imagined encounter was meant, as was often the eighteenth-century case, to expose how "unnatural" was priestly celibacy and by contrast how "natural" was the expression of sexuality, freed of artificial social constraints.

While seeming to provide testimony about hospitality, such a story indicates rather how it had now moved to a kind of backdrop for other, more pressing issues. The story can actually be read as working in ways that conflict with hospitality. There is, first of all, the desire to impose a particular way of living on the visitor. In Diderot's haste to criticize Europeans who have chosen artificiality in place of their authentic natural selves, he depicts a hospitality in which concern for the stranger falls by the wayside. The host might as well force forbidden food onto the guest. Second, the guest is being used as a way of achieving that to which the local family aspires: an infant for the youngest daughter. The guest, in other words, is being used as an instrument, a "means" as the Enlightenment philosopher Immanuel Kant would say, rather than an end.

Such a fanciful story-to-score-an-ideological-point helps focus on a fundamental issue – the need for discussions of hospitality to preserve a balance between two important dimensions: (i) actual empirical studies, as exemplified in ethological/sociological/historical research, and (ii) the general philosophical context within which the discussions take place. The latter emerges most prominently in questions relating to the branch of philosophy called "philosophical anthropology," the attempt to arrive at a successful generic description of the human condition. The Spanish-born American philosopher, George Santayana (1863–1952), identified an important shift in human self-understanding, one which is central to determinations about what hospitality involves and how central it is. The mind of Modern, i.e., post-Renaissance, humans, as he put it, was "a sedentary city mind," not a "pilgrim mind."

Hospitality was central for Homer's characters because Odysseus was a wanderer. Bedouin hospitality is renowned because the Bedouin also are wanderers. Dante, definitely a pre-Modern, and living in a culture dominated by the humans-as-pilgrims theme, reserved the deepest circle of hell for those who were "traitors to their guests or host." Pre-Renaissance Europe in general worked within a framework which thought of humans as wanderers. Within such a context, it makes sense

that hospitality would be considered of central importance. People on the move need food and shelter. By contrast, in cultures for which the central understanding of humans is as homedwellers, such an emphasis fades to the periphery. The framework of philosophical anthropology takes on special importance here. Hospitality will be given a central role when humans think of themselves as inherently wanderers, strangers, and pilgrims. It will move more to the periphery when humans understand themselves as fundamentally homedwellers.

Hospitality: Optional Virtue or Ethics Itself?

With regard to the ethics/hospitality relation, two extremes are represented by the philosophers Elisabeth Telfer (1936–) and Jacques Derrida (1930–2004). Telfer, reading the contemporary world realistically, reports that hospitality now falls under the heading of entertainment. It is a term most used in the context of entertaining friends. What comes to be central in such cases is reciprocity. Friends are involved in a series of mutual exchanges, exchanges which weave and strengthen preexisting links. As such, it continues to be considered a virtue, but an "optional" one. If two circles were drawn, one representing hospitality and the other ethics, there might or might not be an overlap. Life is made more pleasant by entertaining friends. This should not be confused, however, with living a good life in the highest sense. Other virtues are more central and not optional. Words have meanings which emerge at particular places and times. Attempting some artificial extension of what is today called "hospitality" would involve simply stipulating artificial meanings. Friendship and the entertainment that accompanies friendship do make life more pleasant and happy. What should be avoided is confusing this kind of entertainment with the more important considerations involved in what it really means to live a good life.

At the other end of the spectrum, Jacques Derrida is categorical: "Ethics is hospitality." Ethics,

for him, is nothing less than an optimal mode of inhabiting the world. Such a habitation may, on the one hand, be characterized by the kind of border policing associated with wall-building and closing in on isolated communities. Or, it may involve a kind of openness and willingness to welcome the stranger who is genuinely other. This is the practice that most fully deserves the name “hospitality.” Here, Derrida goes beyond ordinary usage and does indeed stipulate a wider sense which he wishes “hospitality” to accommodate. For him, “hospitality” marks a certain mode of being in the world. Food is central, as it is when hospitality is understood primarily as entertaining friends. In this case, however, the prototype case becomes feeding the hungry stranger.

Hospitality: Contemporary Issues

The Telfer-Derrida polarity helps identify questions for researchers today. This is because the traditional privileging of hospitality was imbedded in a web of assumptions and values that have come to be questioned. John Winthrop, the Puritan leader sailing across the Atlantic in 1630, continued to be rooted in a pre-Modern, biblical context. Prior to landing, Winthrop delivered a sermon which referred specifically to the hospitality of Abraham and Lot as described in the Bible. Winthrop began his sermon by identifying the human condition as one of differences. Some people will be wealthy, others poor, some powerful, and others in positions of submission. There are reasons for these differences and among them are “that every man might have need of other, and from hence they might be all knit more nearly together in the Bond of brotherly affection. . . .” Winthrop’s continuing embrace of pre-Modern themes, including hospitality, when contrasted with the actual Puritan practices of failing hospitality with regard to nonconformists, well illustrates one contemporary challenge. If the pre-Modern context was so congenial to hospitality, so also was it congenial to rigid class distinctions, divisive religious affiliations, antidemocratic sentiments, and a general

“us versus them” attitude. One important area for intellectual reconstruction then becomes asking whether hospitality can be re-prioritized apart from the kinds of social, political, ethical commitments with which it was often associated. Derrida seems to think so. Telfer would rather preserve the modern values while allowing hospitality a more modest role. Modernity tended to marginalize hospitality while it emphasized rights, democratic aspirations, economic freedom, and social mobility. Secularization and tolerance began to replace rigid religious affiliations. Hierarchies were challenged and egalitarianism came to predominate. This has now become the new context – a context in which, as emphasized by Telfer, hospitality, redefined, has moved from central to optional.

In such a setting hospitality cannot but be dislocated. It certainly cannot take on the central role to which Derrida’s claim of hospitality-as-ethics assigns it: identifying hospitality as the deepest and most important way in which humans relate to their surroundings. Those who might want to follow Derrida’s focus on hospitality must ask how much of the return to pre-Modern ways is a necessary accompaniment of this focus. At minimum, certain questions need to be addressed. Some of the most prominent are the following:

Does ethics need an overarching good? Derrida’s strong thesis seems to think so. Pre-Modern philosophy, in its Medieval version, at least, also answered “yes.” The virtue in that case was love, *caritas*. Aristotle had made *eudaimonia*, human flourishing, play a similar role. Recently Charles Taylor has argued that any consistent mode of living requires what he calls “hypergoods,” some general umbrella ideals which draw humans forward and justify the kinds of choices they make. Post-Modern thinkers tend, by contrast, to worry about those who would promote a single, ultimate good. They prefer to embrace an irreducible pluralism of goods, always somewhat in tension with each other. For them a claim like “hospitality is ethics,” or parallel constructions like “justice is ethics,” or “compassion is ethics” entails an oversimplification of a complicated situation.

Aligned with the first question is one about whether “hospitality” as an accepted good, whether “hypergood” or not, can be extended beyond human-to-human relationships. If hospitality is understood in the ordinary usage sense, as Telfer does, then the issue of dealing with non-humans falls under a separate heading. If, on the other hand, Derrida’s stronger thesis is taken seriously, the next step is to ask what hospitality can possibly mean when applied to the realm of animals, to that of plants, and to the inanimate components of the earth? In *The Odyssey*, hospitality is associated with the sharing of food. That means animals and plants have been either butchered or uprooted and transformed into edibles. Where is the place of hospitality here? Lest this issue of how hospitality is related to the nonhuman life seems artificial, Samuel Taylor Coleridge’s *Rime of the Ancient Mariner* can serve as a corrective. The entire narrative is set forth because the mariner, violating the protocol of hospitality, killed the albatross.

There are also issues relating to the move away from Modernity and its central cluster of concepts: binary classifications, reductionism, social atomism, foundationalism, privileging of purity, and autonomy. Until a new cluster of concepts can come to shape an alternative climate of opinion, it is not clear whether hospitality can/should take any prominent role. The major friend of hospitality, Derrida, tends to derive his inspiration from the philosopher Emmanuel Levinas (1906–1995) who, in turn, drew on decidedly pre-Modern biblical sources. If post-Modern ideas somehow allow for the reincorporation of older, pre-Modern notions, then perhaps the Derrida/Levinas initiative can take hold. Otherwise, the appropriate place of hospitality within a good life remains to be determined.

In general, once again, the question is whether hospitality can be revived within a context which is so alien to the ones in which it has traditionally been celebrated. Can hospitality be prioritized within democratic republics and their emphasis on majority rule? What is its place in societies that have become more and more secular? Can hospitality have any meaning in today’s world dominated by digital relationships

rather than face-to-face ones? Should immigration law be influenced by hospitality? Does hospitality as a virtue impose obligations on guests as well as on hosts? Can hospitality provide fresh perspectives for biomedical issues like euthanasia and abortion?

Such a cluster of questions takes on special urgency in a world where globalization encourages the movement of not only capital but people, one in which refugees (from disease, famine, weather disasters, war, economic devastation, oppression) continue to be a permanent part of the landscape and one whose economic system rewards those willing to engage in multiple relocations.

Summary

Hospitality, food, and ethics are closely intertwined. Wherever there are wanderers, strangers, and refugees, there are people in need of food and people who can feed them. Whether the latter take it upon themselves to do so provides the basic ethical issue. Hospitality is a universal human theme. In the Western tradition, literature and religious texts have been the main mode of expressing its importance and nature. The meaning of hospitality has changed through time. Pre-Modern meanings differ from Modern (1500–1900) ones. Post-Modern attitudes remain as yet undefined. Two main ethical strands are present today: hospitality as an optional virtue (Elizabeth Telfer) and ethics as hospitality (Jacques Derrida).

Introduction

The connection between human ecology and the great theme of food (and human nutrition) is immediately apparent: there is no other living being that changes the environment so radically for its own nutritional needs as the human being. It will perhaps be objected: every living creature tends to alter the ecosystem for their livelihood needs, and this is certainly true. The difference between the human beings and other species, however, is not so much a *quantitatively broader change* in nature (on a larger scale), but in a *qualitatively more profound transformation*: humans have the power to control and dominate the natural world with technology, as Francis Bacon argued (Merchant 2006, p. 518). It is precisely because of this human power that the need to rethink the relationship between humans and their environment arises, starting from the conceptual tool of human ecology – a very recent discipline that has as its theme the impact of the human species on the ecosystem.

The issue of food is such a special interest in human ecology because it intercepts major ecological issues (pollution, changing the landscape, the use of harmful substances, population overcrowding, the waste of natural resources, etc.) and can be a source of resolutions for the same being that causes such problems: the human being.

In this sense, the approach of human ecology is radically different from that of the more famous deep ecology, which “explains the ecological crisis as the outcome of the anthropocentric humanism that is central to the leading ideologies of modernity” (Zimmerman 1994, pp. 1–2) and states that “man could be described as a highly destructive parasite who threatens to destroy his host – the natural world – and eventually himself” (Bookchin 2004, p. 23); in this regard, human beings can easily be seen as a “cancer on the planet,” because of their destructive power, as effectively expressed by Dave Foreman: “Our environmental problems originate in the hubris of imagining ourselves as the central nervous system or the brain of nature. We’re not the brain, we are a cancer on nature” (Foreman 1990, p. 48).

At the same time, however, human ecology also distances itself from shallow ecology, which, by supporting the unconditional superiority of man over other living beings, interprets nature as a supply of more or less finite resources. In this regard, Warnick Fox writes:

Shallow ecology views humans as separate from their environment. Figure/ground boundaries are sharply drawn such that humans are perceived as the significant figures against a ground that only assumes significance in so far as it enhances humans’ images of themselves *qua* important figures. Shallow ecology thus views humans as the source of all value and ascribes only instrumental (or use) value to nonhuman world. (Fox 2003, p. 252)

Food is an appropriate issue by which to assess several ecological theories, including human ecology, because food highlights the tremendous environmental impact of human activities (agriculture, grazing, deforestation, etc.). However, before going any further in this direction, it is first necessary to solve preliminary definitional difficulties regarding the discipline of human ecology and situate human ecology in the broader context of the so-called change of perspective of ecology.

Human Ecology: Definitional Difficulties

The difficulties of defining the discipline of human ecology probably arise because of the imprecise epistemological status of ecology itself.

Ernst Haeckel devised the concept of ecology in 1866 to indicate the study of the relationships between organisms to each other and to their environment. After this concept was slowly affirmed by academics and disclosed to the public, ecology began to give rise to different “ecologies” in the beginning of the twentieth century, each of which investigated a smaller and more specific portion of reality (as opposed to being a global science). In this regard, nowadays it should be more correct to speak of “ecologies” in the plural and not just “ecology” in the singular: numerous specializations within ecological science have emerged with their own specific theoretical foundations. This phenomenon probably finds its own justification in the epistemological status of ecology in general: that discipline is defined as “interdisciplinary,” as it has as its object of investigation the totality of the natural world, an object so rich and varied that it generates questions that can be answered only through the contribution of several disciplines. It is also possible to attribute the birth of such “ecologies” to several causes: the need to respond to different problems with specific methods in a particular area of reality, the influence of different schools of thought on solutions to the same problem, the diversity of the questions posed about this reality, etc. Therefore, there should be no surprise if ecology encompasses questions of biological, philosophical, sociological, physical, economic, or other natures.

“Ecology is the science of relationship between living organisms and their environment,” and, more specifically, “Human ecology is the study of human interactions with the environment” (Terry Rambo 1983, p. 1). Because of the uniquely profound ways in which humans modify their environment, human ecology is central among the different ecologies. Human ecology has attained considerable practical relevance in our time; for example, it has contributed extensively to defining the criteria for urban projects and economic planning. Human ecology has availed itself of the historical, geographical, medical, economic, and social changes that have helped to achieve a complete and articulated frame for the various human needs that once we considered only at a partial level from a variety of

disciplines such as economic geography, hygiene, and epidemiology. Gerald Marten says:

In human ecology, the environment is perceived as an ecosystem. An ecosystem is everything in a specified area – the air, soil, water, living organisms and physical structures, including everything built by humans. [...] Although humans are part of the ecosystem, it is useful to think of human-environment interaction as interaction between the human social system and the rest of the ecosystem. [...] The social system is a central concept in human ecology because human activities that impact on ecosystems are strongly influenced by the society in which people live. Values and knowledge – which together form our worldview as individuals and as society – shape the way that we process and interpret information and translate it into action. Technology defines our repertoire of possible actions. (Marten 2003, pp. 1–2)

From one side, Marten – and with him most of the supporters of human ecology – tends to move away from a reductionist, scientist vision of the human/environment relationship. On the other side, however, he seems to retain a sociobiologicistic perspective, which interprets mankind as a source of values and social experiences and, in this regard, which cannot exceed *the universal quantitative dimension* toward the affirmation of *the qualitative singularity* of every human individual – his uniqueness; the question about the need to affirm the qualitative human singularity – which descends from human freedom – remains, so, open and unresolved (Bruckmeier 2013, pp. 229–234).

The possibility of avoiding Darwinian and sociobiologicistic reductionism of human ecology is guaranteed only by a rethinking of human complexity through anthropological and philosophical instruments (Beltrão 1985) and, therefore, by a deeper reflection on the relationship between human beings and their environment and, furthermore, on the human being with himself.

The Change of Perspective of Ecology

The ecological revolution – or at least ecology understood as *Weltanschauung* or worldview – consisted of a radical change in thinking in which nature is interpreted as a dense texture or web of relationships:

Where modernity brought us the mechanistic or clockwork view of the world, the current transformation is bringing us the web view of the world, that is, the world as a dynamic, comprehensively entwined, co-evolving world. [...] In society, for example, the change is witnessed by the ecology movement. (Goerner 2000, pp. 91–92)

This revolution was carried out primarily by supporters of the movement of deep ecology (Devall and Sessions 1984), who believe that humans should be given the same dignity as other living beings since humans share their ontological status with them. In this way, as Luc Ferry argued, the ecosystem, or *cosmos*, deserves a higher rank of dignity than human beings, because, in the great chain of being, it is the “necessary condition” of everything: nature can get along without human beings, but not the contrary (Ferry 1995). This change of ontology results in a change of vision of reality: it is necessary to adapt one’s perspective to that of the whole ecosystem, since humans do not enjoy any privileged position within the ecosystem (i.e., anti-anthropocentrism). The transition from anthropocentrism to biocentrism thus marks a shift in values (and therefore a change of ethics): the salvation of the ecosystem and the wealth of relationships (the web) that constitute it have a priority over the needs of the human being. The conclusion that one reaches in this context is extremely simple and summarized as follows: (1) the first principle of every living thing that moves is self-preservation; (2) the ecosystem has an ontological dignity superior to each single part of which it is constituted; (3) each part (including the species *Homo sapiens*) may be sacrificed for the salvation (or the well-being) of the ecosystem.

A Further Change of Perspective

Human ecology was born in the second half of the twentieth century in opposition to this holistic and anti-anthropocentric trend. It is constituted primarily as a knowledge aiming to return the human species to the center of the moral universe and hoping to reconstruct the correct relationship of humans with themselves and with other species. Humans are not only a cancer on the planet, therefore, but also the possible cure for this disease; human ecology gambles on human beings

and their ability to build and develop new solutions and not just to destroy what comes into their hands.

Building on a realist conception of humanity, which sees humans as combining egoistic concerns while simultaneously being deeply social, responsible, and caring, human ecology believes that we must start from the reconstruction of the human personality. The human impact on the environment, in fact, is nothing but a reflection of the way of being of humans: a great cultural impoverishment has, indeed, led to the desertification of nature. In this sense, the direction of analysis proposed by human ecology is opposite to that suggested by traditional deep ecology: the individual (man) to the system (the ecosystem) and never vice versa.

The solutions proposed in human ecology put emphasis on the freedom of the individual as a basis to create a more sustainable world and eschew the idea of restricting individuals' freedom in the name of reducing their environmental impact:

In our concern to preserve freedom we ignore the long and painful struggle by which it was achieved and flaunt the safeguards our society has thrown about the dignity of the individual. In our desire to give every individual an equal opportunity we have neglected to take advantage of the differences between individuals which should enrich our society. [...] We secure the best trainers we can for promising horses and dogs but allow our ablest students to idle through our school system. [...] We deplore the increase of juvenile delinquency while doing little to combat the idleness, lack of recreation, and the flood of evil printed material which probably contribute to it. (Sears 1954, p. 960)

If the human species is, in fact, the species which, more than any other, changes the environment that surrounds it, we should start precisely from this and attempt to heal humanity so that its relationship with other living species can become virtuous and non-harmful: human ecology therefore seeks firstly to work on individuals and on relationships among humans and then seeks to affect the relationship of humanity with the environment.

In light of this, the knowledge put forward by human ecology will be interdisciplinary and will aim to integrate their knowledge of "hard"

scientific disciplines with those in the humanities to have a better overall understanding of the dynamics that affect human beings and that motivate them to act in certain ways. For this reason, "human ecology is concerned not only with the present but with the past. [...] And since the present and future of any community are expressions of its past, we may expect the study of archaeology and history to have a practical bearing on the critical question of man's future" (Sears 1954, p. 960). The combination of two different types of knowledge (that of the more scientific ecology and that of the humanities) will enable the discovery of the human dimension that is essential for more sustainably preserving our planet: "Who can better analyze and explain such conditions than the ecologist, trained as he should be to read the landscape? But he must be equipped to analyze the human community and understand the forces at work within it as well" (Sears 1954, p. 963).

Why (Human) Ecology Must Deal with Eating and Food

Eating is a highly cultural activity. At the same time, eating has a huge impact on the environment, both in terms of changes to the territory and in terms of atmospheric pollution. Furthermore, eating – including the production of food and the development of technical strategies to meet an increasingly sophisticated understanding of our nutritional needs – is an eminently human activity. In this sense, the theme of food is closely related to human ecology.

Of those outlined above, ecologists are most concerned with the impact on the environment arising from new human nutritional needs. Improvements in technology and science have made possible a better quality of life – think only of the phenomena of aging and overcrowding in populations, originating in the evolution in the biomedical field – but are also having a greater impact on the ecosystem of the human species; Sears, in the aftermath of the Second World War, wrote:

We are an explosion. For the first time in earth history, a single species has become dominant, and we are it. The power and intensity of our pressure upon environment is without precedent. [...] This also means increasing demand for space in which to live and move and increasing demand for food and other necessities from the space that is left. Man thus becomes his own rival, or rather the victim of his own rival needs. (Sears 1954, p. 959)

The issue of overpopulation (and the consequences arising from this issue, such as climate change and an increase in resources consumption) is among the most discussed topics in the field of human ecology:

Anthropogenic climate change, or climate change for short, is arguably one of the biggest problems that confront us today. There is wide agreement that climate change will affect the lives of all people around the world in areas such as food production, access to water, health, and the environment. Indeed, it has been estimated that millions could suffer hunger, water shortages, diseases, and coastal flooding as a result of global warming. (Liao et al. 2012, p. 206)

In terms of environmental impact, the issue of food production and associated territorial changes is of primary importance: the United Nations Food and Agriculture Organization found that almost 18% of the world's greenhouse emissions come from livestock farming, and more recent estimates indicate that livestock farming accounts for at least 51% of the world's greenhouse emissions. And the world's greenhouse emissions are expected to increase very dramatically. It has also been estimated that almost 9% of human CO₂ emissions are a result of deforestation for the development of pastures, 37% of anthropogenic methane comes from livestock, and 65% of anthropogenic nitrous oxide is caused by fertilizer. There are, besides, considerable negative impacts on water availability and biodiversity. In order to have remarkable environmental benefits, we probably need to reduce the consumption of red meat, since a large amount of these grazing animals are meant for consumption (Liao et al. 2012, p. 207).

Although the problem is clearly identified, solutions are still very controversial. They can be condensed into four main types: (1) behavioral solutions (educational and training activities in

the field of alimentation with low environmental impact), (2) market solutions (legislative and policy interventions that encourage the purchase, transport, and production of certain types of goods), (3) geo-engineering solutions (large-scale manipulations of the environment), and (4) human engineering solutions (manipulations of people to make them less harmful to the ecosystem). About the latter, which might be described as "post-human," Liao argues: "While reducing the consumption of red meat can be achieved through social, cultural means, people often lack the motivation or willpower to give up eating red meat even if they wish they could. Human engineering could help here. Eating something that makes us feel nauseous can trigger long-lasting food aversion" (Liao et al. 2012, p. 208).

Regarding the market solutions, an "anthropocentric-utilitarian" option is given within the scope of the liberal economy: the so-called ecology market (Anderson and Leal 2001). The philosophical assumption that motivates these solutions is that humans have a natural tendency to be moved by self-interest. The resolutions proposed by "ecology market" are configured as pragmatic, which are not based on the enunciation of universal principles but on actual practices, starting with the rules of the market itself, that will make the market more sustainable. While the "ecology market" emphasizes positive stimuli related to prices, profits, entrepreneurship, and political environmentalism, it also proposes negative stimuli related to legislation and taxes. Far from seeking "zero impact," the "ecology market" aims to make "an impact with a positive sign"; to seek "win-win" solutions, advantageous to all economic, environmental, and social groups; and to do so starting from an authentically human dimension such as the need for private property.

A Model of Nutrition: Food Sharing and Cooperation

The speculations of human ecology on human nutrition (and on the environmental impact of human activities) often arrive at pragmatic solutions but often run aground when confronting ethical dilemmas that do not seem to allow

optimal compromises: consider the well-known – but difficult to resolve – dilemma of “Feeding People Versus Saving Nature” (Rolston 2003).

One of the most reliable and efficient solutions to Rolston’s dilemma offered by human ecology focuses on “Food sharing and cooperation” (Borgerhoff Mulder 2003). This approach focuses on the more general question: “Why do individuals give valuable resources away to others? To give or not to give is a special case of a more general dilemma: why do individuals engage in acts that incur personal costs and benefit others?” (Gurven 2004, p. 543).

The more general question is answered by appealing merely to cost/benefit calculations regarding the individual’s own interests, without having to introduce metaphysical items:

Individuals give for two reasons. One is to get a benefit back. The other is to avoid a cost. “Cooperation” theories stress mutual benefits. “Conflict” theories stress costs. Hunters may give up part of their hunt because they get favours back, or because the recipients are stronger than they are and the hunting isn’t as good anywhere else. (Betzig 2004, p. 561).

There are four main types of “food sharing” (Gurven 2004): (1) kin selection-based nepotism (KS), (2) reciprocal altruism (RA), (3) tolerated scrounging or theft (TS), and (4) costly signaling (CS). All of these models, albeit for different reasons, highlight as the common denominator the need for human beings to share their experiences or to share their own needs, and first among these is the one of self-preservation. In effect, if the Darwinian struggle for survival and the pursuit of utility at any cost will almost certainly lead to a loss of nature (without solving the problem of feeding *all* the people), perhaps cooperation and altruism can offer an effective solution to Rolston’s dilemma.

Human Ecology and Food: The Three Directions

The issue of food – even apart from belonging to the domain of sociology and behaviorist ecologies – is highly relevant for human ecology, the discipline that deals with the rediscovery of human nature.

The issue of food is central to human ecology because it intercepts in an exemplary manner the three directions of the human relationship: (1) the relationship that humans build with the environments in which they live (and thus, the impact of agriculture on the ecosystem, the consequences of their technological choices, the interventions that they decide to undertake, be they on a small or large scale, etc.); (2) the relationship that the individual human being interweaves with other human beings (i.e., the possibility of sharing needs, of devising shared solutions and appropriate policies, etc.); and (3) the relationship that every human individual builds in dialogue with himself or herself (the virtues that one can develop, the values that one discovers to be essential, the priority assigned to different goods, etc.).

It should be noted that denying the last dimension – i.e., the one that describes the relationship of each individual human being with himself or herself – means denying human ecology and, ultimately, supporting deep ecology or shallow ecology, according to which humans are not seen as the solution to the current ecological crisis, but the cancer or the master of the ecosystem.

Summary

The issue of food is a special interest in human ecology – a very recent discipline, with an imprecise epistemological status – because it intercepts humanity’s relationship with the environment. Moreover, it brings to light many major ecological issues and finds a source of resolution for them in the same individuals that cause the problems: human beings. This approach is different from deep ecology, which sees human beings as a cancer on the planet: the solutions of human ecology depend on human beings and their ability to develop new answers, putting emphasis on the freedom of the individual as a basis for creating a more sustainable world. Eating is a cultural activity (and, in this regard, an eminently human activity) but with a huge impact on the environment: among other issues, overpopulation is

widely discussed in human ecology. However, solutions are still very far away, although proposals can be grouped into four main types: behavioral solutions, market solutions, geo-engineering solutions, and solutions of human engineering. Among the most reliable and efficient solutions offered by human ecology is that of “food sharing and cooperation,” which is a compromise between the two main aspects of human nature: the utilitarian and the social. The issue of food is so central to human ecology because it intercepts in an exemplary way the three directions of the human relationship: with the environment, with other human beings, and, finally, with oneself.

Introduction

Access to food and water is a matter of intense individual concern. Healthy people who go without food and water for 48 h will find that intense feelings of hunger and thirst are motivating them to find and consume some food and water. Ensuring food access for everyone is also a long-standing matter of moral, social, and political concern. Inadequate access to food and safe water is still a human problem; roughly 800 million people currently do not get enough food to cover their energy requirements (FAO 2013). Today we talk about food access not just as a development goal (the first Millennium Development Goal is “Eradicate extreme poverty and hunger” (United Nations 2000)) but also as a human right – “the fundamental right of everyone to be free from hunger” (International Covenant on Economic, Social and Cultural Rights, United Nations 1966).

Human rights are an important resource for ethical reflection about food and agriculture. This entry first discusses the right to food as it is developed in the international human rights movement. It then turns to philosophical discussions of access to food in work by authors such as Peter Singer, Henry Shue, Amartya Sen, Martha Nussbaum, John Rawls, and Thomas Pogge. The third section relates the human right to food to issues about agriculture, population, and the environment.

Human Rights and the Right to Food

Human rights are legal and/or ethical norms that aspire to protect all people everywhere from

severe political, legal, and social abuses. The main sources of the contemporary idea of human rights are found in the natural law and natural rights tradition of philosophical thought, the bill of rights tradition that begins with the Magna Carta, and the declarations and treaties created by international organizations such as the United Nations, the Council of Europe, the Organization of American States, and the African Union.

The contemporary human rights movement began in 1948 with the approval of the Universal Declaration of Human Rights (United Nations 1948). Subsequent human rights treaties include the European Convention on Human Rights (1950), the International Covenant on Civil and Political Rights (1966), and the International Covenant on Economic, Social and Cultural Rights (1966).

The Universal Declaration included “economic and social rights.” Among these was Article 25.1, “Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food. . .”

Human rights norms use the concept of an individual *right* to something. Rights are normative guarantees of access to some freedom, power, protection, or good. Examples of human rights include the right to freedom of religion, the right to a fair trial when charged with a crime, the right not to be tortured, the right to equality before the law, and the right to an education. A description of a right with associated duties should cover at least:

1. The *rightholder* (the party or parties who have the right)
2. The *object* of the right (what the right is *to*)
3. The *dutybearer* (the party or parties with duties or responsibilities under the right)
4. The *normative content* of the right (what the dutybearers are required to do to make available the object of the right and what the rightholder may do to activate and gain compliance with the right)

When we apply this framework to the right to food, we can say that, first, the rightholders are all people. Second, the object of the right to food is nutrition and hydration adequate for health and

normal functioning. Third, the primary dutybearers are the governments of the 200+ countries into which our planet is divided. Individuals and international organizations may also have responsibilities under this right. Finally, the normative content of the right specifies when the right applies (when the rightholder cannot obtain adequate food and water through his or her own reasonable efforts), how the rightholder can activate and use the right, and the forms in which access to food and water must be provided by the dutybearer (cash payments, food cards, highly subsidized products, etc.).

Of the various economic and social rights, the right to food and the right to education are the most widely accepted. Famine and malnutrition are now widely recognized sources of moral, political, and legal obligation. Further, the right to food has canonical formulations (described below) in international treaties and national bills of rights and is seriously promoted by international agencies, international diplomacy and relief efforts, and NGOs.

When the rights in the Universal Declaration were made into treaty law in 1966 by two UN treaties, one of these, the International Covenant on Economic, Social and Cultural Rights, elaborated the right to food in Article 11:

The States Parties to the present Covenant recognize the right of everyone to an adequate standard of living for himself [sic] and his family, including adequate food, clothing and housing. . .

Under this right, countries have duties to (1) ensure that food is available to all their residents; (2) improve agriculture, food processing, and food supply chains; (3) teach people about nutrition; and (4) help create an international system that assists countries with food production and provides emergency assistance. Contemporary human rights documents put great emphasis on nondiscrimination in relation to all rights so we could add the following: (5) ensure that access to food is not based on discriminatory grounds such as gender, race, religion, or caste.

The UN committee that supervises compliance with this treaty, the Committee on Economic, Social and Cultural Rights, also works to develop and clarify the content of each right by publishing

interpretive comments. In 1999 the Committee issued “General Comment 12” on the right to food, which includes the following:

The content of the right: “The right to adequate food is realized when every man, woman and child, alone or in community with others, have physical and economic access at all times to adequate food or means for its procurement.”

Food safety and cultural acceptability: Food should be available in “quantity and quality sufficient to satisfy the dietary needs of individuals, free from adverse substances, and acceptable within a given culture.”

Duties under this right: “Every State is obliged to ensure for everyone under its jurisdiction access to the minimum essential food which is sufficient, nutritionally adequate and safe, to ensure their freedom from hunger.”

Duties to regulate non-State actors: Violations of the right to food can occur through the direct action of States and also other entities such as individuals and corporations insufficiently regulated by States.

Comprehensiveness and sustainability: Efforts to satisfy this right should address “all aspects of the food system, including the production, processing, distribution, marketing and consumption of safe food. . . Care should be taken to ensure the most sustainable management and use of natural and other resources for food at the national, regional, local and household levels.

Priority to the most vulnerable: “Even when a State faces severe resource constraints. . . measures should be undertaken to ensure that the right to adequate food is especially fulfilled for vulnerable population groups and individuals.”

Ethical and Philosophical Work on the Right to Food

Work on the right to food by international lawyers and diplomats has been accompanied – and sometimes influenced – by the work of philosophical theorists.

Because access to adequate food and water is a condition of survival and well-being, and a subject of human rights, it has received considerable attention from contemporary moral philosophers. Peter Singer's (1972) essay, "Famine, Affluence, and Morality," provides a good starting point. It responded to a famine in Bengal and defended a duty of people in developed countries to provide effective assistance – even when the hungry people are in distant lands. Singer's approach was not based on human rights; it was rather based on a consequentialist principle that "if it is in our power to prevent something bad from happening, without thereby sacrificing anything of comparable importance, we ought morally to do it" (Singer 1972).

Henry Shue's 1979 book, *Basic Rights*, argued that subsistence (which included adequate food and water) was a basic right in the sense that no other rights could be enjoyed in its absence. Shue argued that "Deficiencies in the means of subsistence can be just as fatal, incapacitating, or painful as violations of physical security. The resulting damage or death can at least as decisively prevent the enjoyment of any right as can the effects of security violations" (Shue 1980, second edition 1996).

Amartya Sen has played a major role in influencing how people think about food and development. He urged shifting the focus away from "commodities" (the availability of goods and services) and toward people's "capabilities," what people are actually able to do and be (Sen 1985). Sen argued that adequate food cannot be understood in terms of a particular number of calories or a fixed quantity of some commodity such as rice; it should rather be understood in a way that is appropriate to one's capabilities, situation, and choices. Sen pioneered a capabilities-oriented approach to development that he calls "development as freedom." In this view, freedom is conceived as having both negative and positive dimensions (Sen 1999). Sen's work on famines has also been important. He noted that famines often occur in locations without severe overall food shortages and argued that famines are generally best understood as problems of inadequate purchasing power – as matters, that is, of low

capabilities (Sen 1981). Sen also argued that democratic institutions, and particularly freedom of the press, play a large role in preventing famines (Sen 1982). Both Sen and Martha Nussbaum have argued that unequal access to food is a major source of the problem of "missing women" (a significantly lower percentage of women than men in the population) in India and elsewhere (Nussbaum 2000).

In his much-discussed work, *The Law of Peoples*, John Rawls developed a view of international human rights that takes the right to life to include access to the means of subsistence (Rawls 1999, p. 65). Rawls also addressed the inability of "burdened societies" to provide for the basic needs of their citizens by endorsing a limited duty of international assistance (Rawls 1999, pp. 5, 115–126).

The most extensive recent philosophical treatment of food and human rights is found in Thomas Pogge's *World Hunger and Human Rights* (Pogge 2002). Pogge reminds us that nearly a billion people today live in severe poverty and that such poverty causes tens of thousands of deaths every day. He views these deaths as a major human rights violation that could be avoided if the contemporary international system were reformed.

Pogge emphasizes UDHR article 28 which says that "Everyone is entitled to a social and international order in which the rights and freedoms set forth in this Declaration can be fully realized." Pogge argues that the current international system plays a substantial role in creating and maintaining world hunger and that consequently wealthy countries – and their citizens – have not just a relatively weak duty of aid, but a stringent duty of justice to take decisive steps toward the eradication of global poverty. He holds that both countries and individuals have a duty not to be complicit in an international order that unfairly disadvantages poor countries and the people in them. Countries have such a duty, Pogge suggests, because they have violated the *negative duty* not to contribute to the imposition of a global institutional order that foreseeably and avoidably renders unfulfilled the most basic socioeconomic rights. Pogge goes to great lengths to refute the view that most of the causes of severe national

poverty come from inside the countries that suffer it and argues for the urgent need for three feasible “reforms of the global institutional order that would each dramatically reduce existing poverty-related human misery.” Pogge named the three main international causes of poverty “the three Ps”: Protectionism, Privileges, and Pharmaceuticals (Pogge 2002, p. 263).

Agriculture and the Human Right to Food

For the right to food to be realized worldwide, agriculture has to do its part by producing food of sufficient quantity and quality for the large human populations that exist today. As we saw above, the ICESCR addresses issues of food production, storage, and affordability. Numerous ethical and policy issues come into play as we think about what people should eat, how land should be used, high-tech innovations in agriculture, the conditions of agricultural work, the environmental dimensions of food production, and international food assistance. Most of these issues have not been and probably never will be addressed by human rights documents. Interaction between people who work on human rights and people working on agricultural policy is uncommon but does occur within the World Bank and in the United Nation’s Food and Agriculture Organization (FAO).

The human right to food cannot be sustainably realized without agricultural success. Current trends that threaten such success include:

1. World population is now around seven billion and is expected to increase by another billion or two in the coming decades (United Nations 2012). Much of this growth will occur in the least developed countries.
2. Climate change will be a challenge to agriculture in many ways, particularly since agriculture relies heavily on fossil fuels and contributes significantly to deforestation as savannas and forests are converted to fields and pastures.
3. Subsistence farming on small plots has become difficult or impossible in most countries.

Successful agriculture is increasingly high tech and large scale.

4. Agricultural land, water, and workers are increasingly used for the production of non-food products such as lumber and biofuels.

Summary

International human rights, and particularly the right “to be free from hunger,” provide an important resource for ethical reflections about food and agriculture. Another important resource is writings about freedom from hunger by philosophers such as Singer, Shue, Sen, Nussbaum, Rawls, and Pogge.

Introduction

This entry is concerned with the array of physiological and psychological states that distinctively promote, accompany, and follow the human act of eating. This array of states is here referred to – in a technical way – as “hunger.”

Hunger is arguably the most important concept in the study of malnutrition, undernutrition, and famine. A study of hunger is hence a crucial step toward framing philosophical questions pertaining to the ethics and politics of food access and dieting, subjects to be addressed in the second section of this entry. Hunger can also be approached from an existential point of view, as a defining aspect of the human condition. Through this lens, hunger raises little-explored philosophical difficulties, to be pointed out in the first section of this entry. Finally, an appreciation of the complex facets of hunger is relevant in high-end gastronomy and makes a difference to the aesthetic value of a dining experience, as shall be discussed in the third section.

The terms by means of which we express, attribute, or theorize hunger are relevant to framing its study and demonstrate the variety of its cultural understandings across history and world regions. Each natural language has a wide range of expressions signifying (some of) the states correlated with the human act of eating, and it is interesting in itself to study how languages differ from and resemble each other in this respect. For instance, English vocabulary includes *hunger*, *famine*, *appetite*, *craving*, *disgust*, *starvation*, *gluttony*, *distaste*, *longing*, *need*, *desire*, etc. To any such list, one should add the rhetorical figures expressing physiological or psychological states correlated with the act of eating; the most recurring examples in this class involve metaphors or analogies, such as *I could eat a horse* or *I am as hungry as a bear/wolf* or *He is a pig* (said of a person who eats sloppily or too much) and *She eats like a bird* (for someone who eats very little), or consider the expression *pig out* to express some forms of overeating and the expression *to wolf down food*, to signify extreme voracity in eating.

The range of linguistic expressions correlated with the human act of eating has not been systematically studied. We have evidence that children

learn a subset of such expressions early in their linguistic development, along with expressions referring to inner physiological states (studies in developmental psychology show that words relating to such states (*hungry*, *tired*, *sleepy*) tend to be acquired before words having a more cognitive flavor, like “knowing” or “believing”; cf. Doherty 2008; Taumoepeau and Ruffman 2006). But the range of vocabulary used to convey hunger states is vast, and it also includes sophisticated expressions, or expressions typical of specific subcultures or *milieus*, so that it cannot be affirmed that all the hunger-related expressions are learned early in life.

We can furthermore point out important etymological and semantic variations. To stay within the English language, the noun *hunger* is of Germanic origin, and its cognate expressions may be traced as far back as Sanskrit (*kakate*, to thirst); *appetite* is typical of Romance languages, has a Greek origin, and its cognate expressions can be traced as far back as Sanskrit (*patram*, wing) and Hittite (*pattar*, wing); but the history of the word *famine* is less clear and can be traced back only to its Latin roots. At the semantic level, an agent *experiences* famine but cannot *have* it; yet an agent *has* appetite and does not *experience* it; and – in some languages, though not in English – she can both *have* and *experience* hunger.

The ways in which such etymological and semantic variations do and should constrain a theory of physiological and psychological states correlated with the human act of eating have not been assessed. In fact, such theories themselves are lacking, by and large. Scholarly efforts have dealt with only selected aspects of the topic, such as the physiological effects of undernutrition (Keys et al. 1950), the psychology of mindless eating (Wansink 2006), the social causes of famine (Sen 1983), and its metaethical implications (O’Neil 1980; Singer 1972).

The Philosophical Significance of Hunger

Hunger is a primary mode of being. We are born hungry. We have been hungry well longer than we

can remember being alive and well before gaining self-consciousness of our own pleasures. Each human, *qua* human, is endowed with an array of physiological and psychological states correlated with the act of eating; the satisfaction of hunger is one of the most complex and important ecological relationships in which we partake. The irreducible nature of hunger was once well expressed by French philosopher Emmanuel Levinas (cf. also Wurgaft forthcoming): “It is not really true to say that we eat in order to live, we eat because we are hungry [...] The need for food does not have existence as its goal, but food” (*Existence and Existents* 1978: 37).

Hunger is clearly related to (if not identical with) a complex array of neurophysiological states. Some of these states are independent of the will (e.g., trivially, we are hungry while still in the womb); and yet, we cannot say that being hungry is just an automatic bodily mechanism, as is the work performed by the lungs. You can learn to control your hunger: you can resist it, you can train to contain it, and you can make efforts to become hungry. As neurogastroenterologists have shown, human hunger is neurophysiologically far more complex than the hunger of other animals (cf. Gershon 1998).

Hunger’s essential ties go beyond those to our senses, bodies, and brains. Because it can be managed in various ways (e.g., trained, resisted, stimulated), hunger is part of the world of *culture* too. Many of the complex facets of hunger are culturally transmitted (e.g., via upbringing or advertisements). Learning how to manage hunger is part of one’s education, and the ways in which we come to terms with it reflect (sometimes arguably *express*) a wealth of personal and collective values, beliefs, and desires. In connection to those remarks, an important example is the negotiation of our appetites in order to dine with others. The extent and the modalities within which we are willing to modify our diet for the purposes of attending a party or a reception, or for sharing food or an experience with someone, are at the core of a long-standing dispute over the ethical, political, and civic implications of our diet. It is only under this perspective that we can make sense of the fierce opposition against Luigi

Cornaro's *De Vita Sobria (On a Temperate Life)* (1634) on the part of figures such as Nietzsche (in the *Twilight of the Idols*) (2007)) Cornaro's book was advocating a strict and disciplined diet, thereby propagating an ascetic attitude that prevented his followers from engaging with their societies as freely and vigorously as they should.

Hunger is correlated with a wide array of pleasures. Some of these are hardly controllable, such as the palatal pleasure provided by a fatty and sugary food (e.g., a bite of ice cream or chocolate); some are highly refined, such as the appreciation of a slight variant in a recipe, say a touch of French tarragon on eggs Benedict. Some pleasures are long lasting, like the memory of a dish at a three-star Michelin restaurant; some are ephemeral, such as the satisfaction of an undifferentiated longing for *something salty*. And yet, hunger cannot be equated with pleasure, for at least two reasons. First, hunger – unlike pleasure – is deeply entangled in our relationship to what is not us. Second, hunger is part of the lives of those who may not feel pleasure or may do so in a far different manner, such as early-stage fetuses or humans in a vegetative state (for instance, the part of the brain connected to the stomach continues to function even in a vegetative state). In this sense, one could contend that *hunger is more fundamental than pleasure for the human condition*.

A (contemporary) philosophy of hunger is yet to be developed (cf. Leder 1990 for an original attempt), and the subject itself has arguably been ostracized by the philosophical establishment for centuries (see Shapin 1998). Nevertheless, it seems plausible to imagine a view according to which hunger is at the root of the human condition. It is in the ways that humans experience hunger that one can trace our identity as beings. Eating in humans lies at the intersection between evolutionary history, ontogeny (individual development), behavioral evolution, and symbolic evolution. More specifically, in eating we find not only the characteristic function of living entities (i.e., metabolism) but also a point of convergence between the rational and emotional aspects of human agency, as well as the point of convergence between humans as biological organisms and as

expressions of a culture. (It should not surprise us that authors such as Descartes, Locke, Leibniz, Hume, and Kant did not come to think of hunger as a state distinctive of humans, since they lacked the biological and evolutionary insight that made such distinctiveness specific.)

Thus, on hunger one could hope to rest a philosophy that is antagonistic to the Cartesian model – hunger is a primary mode of being, yet, unlike Descartes's *cogito*, it is *not* a pure intuition – as well as to utilitarian theories resting on pleasure: hunger is a primary mode of being, yet it is *not* hedonistic. If hunger is taken as a paradigm of the human condition, then at least two significant consequences ensue. First, the most appropriate metaphysics is a relational one – since eating is a relation – as opposed to a metaphysics of individuals, each of which is defined in terms of intrinsic or essential properties. Second, rational reflection would cease to have a foundational role, yielding to the array of entangled mind-body states related to hunger; rational agency would become the special case of human agency in which an action is highly independent (yet never completely independent) of the performing body.

Hungry Bodies, Hungry Souls, and Disordered Hungers

The centrality of hunger to the human condition serves to introduce and explain the so-called omnivore's dilemma (cf. Fischler 1988; Pollan 2006). Any human has to eat in order to survive; humans are omnivores and, moreover, can go without eating for weeks; hence, in virtually any circumstance in which foods are supplied to a human, she will be confronted with the choice of whether or not to eat them, and which ones to consume.

To do justice to our topic, it is very important not to trivialize the dilemma by viewing it as either a physiological *or* a psychological dilemma. It is tempting (and customary) to believe that some humans have a *hunger problem*, namely, the problem of finding sufficient nutrients to (potentially) live a healthy life, while others

have an *appetite dilemma*, the problem of choosing what to eat and avoid being tricked by their palate; the hunger problem is physiological, while the appetite dilemma is psychological (on the modern history of the idea of hunger, cf. Vernon 2007). This is a fundamentally misleading representation of the human relationship to food consumption, because it purports to isolate certain aspects of the experience of eating, confining them to either the level of physiology (hunger) or psychology (appetite). Any act of eating, however, involves multiple intertwined layers, spanning from extremely complex neurophysiological mechanisms to a vast spectrum of hedonistic responses and a huge spectrum of cultural connotations. Eating, in other words, is not simply a matter of need vs. excess, no matter how sophisticated our analysis of such concepts (for an attempt to disentangle different concepts of need, cf. Wiggins 1987). The act of eating encompasses physiological, psychological, hedonistic, and broadly cultural aspects of the self, which cannot be bracketed in a hunger vs. appetite and physiology vs. psychology dichotomy. Hence, the omnivore's dilemma involves both what is commonly called "hunger" and what is called "appetite" and embraces any occasion of eating. Indeed, the author who first theorized the dilemma, Claude Fischler, introduced it to study the relevance of the act of eating to personal identity.

The omnivore's dilemma serves to stress the common roots of different conceptions of hunger, which are at play in humanitarian efforts, theoretical psychology, and clinical practice. We shall survey each of these conceptions, in order.

Hungry Bodies. The topic that is most readily associated with the word "hunger" is food deprivation, as connected to famine, war, and economic poverty; we may refer to this topic as the study of hungry bodies (cf. Sen 1983; O'Neil 1980). Hungry bodies have been a subject of research throughout the history of medicine, providing precious information to tackle issues such as infertility (Toulalan 2014), curing of disease (Williams 2012 and Carlson 1916), and longevity (Keys et al. 1950); hungry bodies occupy a special place in the history of economics too, beginning at least with Malthus's *An Essay on the Principles*

of Population. At the turn of the twentieth century, the physiology of hunger was an up-and-coming field of academic research; important data for the study of the physiology of hunger were collected in extreme situations, most importantly during World War II, in the Warsaw Ghetto (Tushnett 1966), and during the so-called Great Starvation Experiment (sometimes also referred to as the Minnesota experiment, cf. Tucker 2007). Current data on hungry bodies are lacking, mostly due to the ethical restrictions on data collection (it is not morally acceptable to ask a patient to starve, and you cannot collect data from people who are starving, no matter the reason). Also for this reason, the physiology of hungry bodies is not a popular topic in the growing field of food and nutrition studies, and the most important work is more quietly carried forward in a few selected labs around the world (cf. Russell 2005, Chapter 1; cf. also Le Magnen 1985, a volume published at a moment of high hopes and expectations for the study of hunger).

The most sophisticated and influential contemporary publication for the study of hungry bodies is the Global Hunger Index (GHI). This is a yearly report jointly published since 2006 by the International Food Policy Research Institute (IFPRI), Welthungerhilfe, and (since 2007) Concern Worldwide. The GHI provides a multidimensional measure of global hunger. The concept of hunger it adopts is borrowed from FAO: "Hunger is usually understood to refer to the distress associated with lack of food. The Food and Agriculture Organization of the United Nations (FAO) defines food deprivation, or undernourishment, as the consumption of fewer than about 1,800 kilocalories a day – the minimum that most people require to live a healthy and productive life" (von Grebmer et al. 2015, p. 8, box 1.1). The distress associated with the lack of food is analyzed in terms of two further concepts: undernutrition and malnutrition. *Undernutrition* "goes beyond calories and signifies deficiencies in any or all of the following: energy, protein, or essential vitamins and minerals" (von Grebmer et al. 2015, p. 8, box 1.1). *Malnutrition* "refers more broadly to both undernutrition (problems of deficiencies) and overnutrition (problems of unbalanced diets,

which includes consuming too many calories in relation to energy requirements, with or without low intake of micronutrient-rich foods)” (von Grebmer et al. 2015, p. 8, box 1.1).

Contemporary tools used to study hungry bodies bracket the psychological, identity-related, ethical, and political dimensions of hunger. Researchers have thus inadvertently fueled the myth of a hunger problem, which stands in opposition to the equally artificial understanding of the omnivore’s dilemma as being experienced by the lucky individuals who do not suffer food deprivation. The disastrous effects of these misconceptions can hardly be underestimated. For one, they lead to misguided humanitarian efforts that inadequately appreciate the nonphysiological dimensions of food deprivation. But most importantly, they divide the world of bodies into two classes – those that are hungry and those that are not – thereby obscuring the connection between undernutrition and overnutrition, which jointly afflict the poorest sectors of societies on a global scale. (Typically, societies that overcome the first become at high risk for the second, as the case of the United States well illustrates.)

Hungry Souls. The complex effects of hunger on human behavior have been of interest to a wide variety of scholars, including anthropologists, economists, evolutionary psychologists, and sociologists. The study of hungry souls is typically treated as the study of human *appetites*, where the terminological choice of “appetite” is meant to stress the possibility of a choice and the likelihood of a perceptual error in estimating what our bodies “need.” At least since the introduction of the concept of a calorie, appetite started being seen as an obstacle, rather than a guide, to good dieting. Indeed, multiple lines of research aimed at pointing out the ways that human appetite can be stimulated and oriented, stressing the automatic and uncontrollable mechanisms through which humans come to introject food. For instance, an important strain of research theorizes that humans are *addicted to food* (Ziauddeen and Fletcher 2013), that is, that food intake is akin to drug intake, so much so that a great deal of our eating behavior can be shown to be mindless (cf. Wansink 2006). Data collected in the study

of appetites have been used for different and often conflicting goals, such as, for instance, lowering the obesity rate and shaping food marketing strategies in the same population

Unlike the perspective adopted in the study of hungry bodies, the study of hungry souls does not dissociate the psychology of eating from its physiology. In fact, the most notable findings concerning human appetite have come from the study of the physiological mechanisms connected to eating. However, the study of hungry souls has bracketed the most fundamental aspects of the ethical, political, and identity-related dimensions of hunger. The extent to which identity and values affect the way we eat can hardly be quantified; but these effects are obvious in the taboos and aversions that populations have concerning certain foods. To fulfill our appetite is not simply to fulfill a momentary wish; it feeds our souls in ways that intimately connect us to those who do not have the privilege of satisfying their own appetite. Thus, the study of hungry souls has by and large failed to appreciate the value of fasting (adopted in most food cultures) or the value of staying hungry in order to have a balanced relationship with our body (also widespread in several food cultures). In fact, most contemporary diets prescribe which foods must be consumed, not the *mindset* in which they are consumed. We focus on the foods, regarding human behavior as a mechanism, overlooking the plasticity of human hunger as well as its ethico-political dimension.

Disordered Hungers. Lastly, an important chapter in the study of hunger concerns eating disorders, such as anorexia, bulimia, and orthorexia. This is where the absence of a link between the study of hungry bodies and hungry souls is most harmful. Clinical practice addressing eating disorders is timidly sustained by theoretical conceptions of hunger, which connect eating choices (“appetites”) with the core of individual identity. For instance, eating disorders have historically targeted women, demonstrating how certain forms of appetite can showcase oppression and lack of power; and, yet, current theories of appetite are unable to explain the links between socio-political roles and eating behavior, while current studies of hungry bodies discard eating disorders

as issues that are outside the sphere of political concern for humanitarian efforts (cf. Giordano 2005 for an overview of the ethical issues connected to eating disorders). A theoretically unified understanding of hunger could help provide a foundation to clinical practice, a model through which individual agents could represent their agency and parallel it to other, more “ordered” ways of eating.

Hunger and the Aesthetics of Food

If dining or drinking has an aesthetic worth that compares to contemplating a painting or a sculpture, watching a movie, a ballet, or a play, or listening to a symphony, then the palate must be placed on a pedestal the like of vision or hearing. Such a move has important consequences for aesthetic theorizing, which have been discussed in contemporary philosophical literature (cf. Korsmeyer 1999; Telfer 1996). For instance, mundane experiences such as a home-cooked meal or a coffee consumed at the bar of a coffee shop may turn out to be of high aesthetic worth. The artistic discourse is, in these cases, broadened to novel spaces, where human agency is seen under transformed lenses. This seems indeed to be the trend, where happenings in restaurants, butcher shops, wineries, breweries, coffee shops, etc., become increasingly intellectualized and fetishized, turning ordinary places into spaces where societal ideals and values are negotiated, changed, and put into question.

In the past two decades, a wealth of philosophical literature has sustained the effort to vindicate the aesthetic worth of gastronomic experiences. Yet current mainstream aesthetics is as far as ever from considering hunger in particular among its major themes for philosophical reflection. In this respect, philosophy parts with other fields. Today, museums and galleries across the globe exhibit a wide spectrum of visual art projects that deal with dieting, starvation, food cravings, and other modalities of hunger; similar considerations apply to literary works and to cinema. The lack of a philosophical analysis of the role of hunger in the aesthetic experience of food is a considerable

shortcoming. Two themes are particularly fitting in explaining how philosophical views about hunger can inform our aesthetic appreciation of food: the first is the role played by hunger in defining gastronomic perspectives, which will be illustrated through the case of *nouvelle cuisine*; the second is the disembodied mindset of a certain contemporary gastronomic criticism. The two themes will be examined in order.

Implicitly, it seems that most cooks do think of their work as a dialogue with the hunger of diners. *Nouvelle cuisine*, famous for its parsimonious portions, seems to be the case that most evidently exhibits such an implicit ideal; other excellent examples would be *kaiseki* meals, evolved around food shortages and proper ceremonials, and *omakase* meals, where the cook tailors a meal to the diners. In 1972, Henri Gault and Christian Millau, two culinary journalists actively engaged in promoting *nouvelle cuisine*, published an influential manifesto in *Vive la Nouvelle Cuisine Française*, containing ten commandments (evidently inspired to the political protests of 1968). Of particular interest for present purposes is the seventh commandment: “*Thou shall not ignore dietetics*. The postwar times of malnutrition are over” (cf. Rao et al. 2003: 817). Although the commandment does not explicitly mention hunger (a term probably never employed in a modern or contemporary food manifesto), it gestures to it through the words “dietetics” and – most remarkably – “malnutrition.” For proponents of *nouvelle cuisine*, a broad consideration of the hunger levels of diners suggested rethinking portions, with the aim of elevating the aesthetic worth of a dining experience. The responsibility of the cook is, thus, to think of the dining experience as a dialogue with the hunger of the diner.

Most contemporary cooks and culinary movements have not explicitly theorized the ways in which cooks should adjust their dishes based on diners’ varieties of hunger. A reflection on hunger in contemporary aesthetics and food criticism would arguably facilitate such theorization.

Moving to the second theme, an important trend in contemporary gastronomic criticism and cooking regards digestion and hunger as accessory companions to our gastronomic experiences.

Tasting for tasting's sake: this seems to be the underlying assumption. For instance, the practice of evaluating wines by observing, sniffing, swirling the liquid in the mouth, and then spitting it out has moved from a shortcut taken by wine producers and connoisseurs to a standard of judgment. Obviously, some of the liquids tasted by producers and connoisseurs are forms of wine in the making (such as must), which do not agree with digestion; also, the occasions or amounts of wines tasted do prudentially call for spitting. But, matters are different for consumers, including critics: it is unclear why consumers should separate digestion from the aesthetic dimensions of wine. Thus, the score assigned to a wine by influential critics such as Robert Parker is not based on an analysis of the digestive and intoxicating powers of the wine. Granted, from the alcohol content, the phenolic properties, and the method of production of the liquid, one could try to guess its digestive and intoxicating powers. But if this matter were of any importance in the judgment, guessing would not be enough (cf. McCoy 2006).

Moving from beverages to food, in high-end gastronomy and in the vast majority of food shows, it is common to find a total neglect of (or even a dismissive attitude toward) metabolic processes. For instance, the starting proposition of cooks of the caliber of Ferran Adrià is that dining at a restaurant has little to do with hunger. People don't go to restaurants because they are hungry. They go to restaurants because they are looking for a tasting experience, which will occasion their aesthetic appreciation of certain foods. To substantiate the idea that metabolism is, as a component of our gastronomic experiences, a mere accessory, we could cite the increasingly near possibility of feeding ourselves with pills or other sorts of products of the pharmaceutical industry. Were such practices to become routine for humans, going to a restaurant would turn into an activity as superfluous to our existence as visiting the Metropolitan Museum or a night at the opera. Hence the idea that the aesthetic worth of a meal rests not at all on its relationship to digestion.

Yet the shortcomings of a gastronomic perspective that limits itself to what happens in the mouth are serious. Chief among these is its

implied conception of gastronomic pleasure. The suggestion is not that hunger is a sufficient condition for the aesthetic worth of a gastronomic experience. Rather, hunger is a key ingredient in providing a gastronomic experience with aesthetic worth. In some cases (probably in the majority of dining occasions), hunger is a necessary condition for assuring that the aesthetic worth of the gastronomic experience is properly appreciated; you would not want to visit the Metropolitan Museum with conjunctivitis, and you would not want to try out an important restaurant after a wedding feast. Similarly, thirst, mild intoxication, and craving for a refreshing beverage seem to be necessary conditions for appreciating the aesthetic worth of several beverages. Granted, there are gastronomic experiences that do not require the consumer to be hungry, thirsty, and the like. Some such experiences may be crucial in the development of our gastronomic taste. Yet it is difficult to see how even such experiences could be meaningful if we were not also comforting and entertaining our hunger, thirst, and the like in a lighthearted way. To dine and to drink ultimately mean to *consume*, and the practice of consuming foods and beverages ultimately rests on our need to metabolize. Compare the significance of eating a piece of freshly baked bread (delivered by a local shop to your apartment) in the following two situations: you have been going without food for days; you have just come out of a wedding feast. It is not only the ethical worth of the gestures that is hardly comparable but also their aesthetic worth, because the two situations involve two distinct ways of being hungry.

Hunger – broadly understood to encompass thirst and specific food and beverage cravings – is the place from which to begin our evaluation of the aesthetic worth of gastronomic experiences. Pleasure from the palate is, then, an activity that acquires meaningfulness in dialogue with hunger. In such a perspective, food aesthetics is a discipline centered on the body of the consumer, on a dialogue between hunger and consumption experiences. This insight is both what has been missing from the contemporary debate on the aesthetic worth of gastronomy and what approaches such as Parker's and Adrià's cannot account for; it is

what a philosophy of hunger can help to develop and theorize. (Work for this entry developed over a period of two years, between August 2014 and August 2016, and was facilitated by a Research and Publication Grant from the College of the Holy Cross. It benefited from suggestions received at several conferences and colloquia as well as from the insights of students in the seminars taught during this period at the College of the Holy Cross and at the University of Gastronomic Sciences. I am much indebted to several friends and colleagues, including Ari Ariel, Rafi Groszlik, Barbara Haber, Nicola Perullo, Steven Shapin, Helena Siipi, Paul Thompson, Joey Tuminello, Corky White, and Ben Wurgaft. Finally, I owe a special gratitude to Naomi Arbit for our long-standing research collaboration on hunger and to Carolyn Richardson for her punctual revisions of an early draft of this entry.)

Summary

The entry is concerned with the array of physiological and psychological states that distinctively promote, accompany, and follow the human act of eating; this array is referred to – in a technical way – as “hunger.” Each natural language has a wide range of expressions signifying (some of) the states correlated with the human act of eating; these expressions have not been systematically studied to date. We have evidence that children learn a subset of them early in their linguistic development, along with expressions referring to inner physiological states; other expressions, typical of specific subcultures or *milieus*, are learned only during adulthood. The first section of the entry approaches hunger from an existential point of view, as a defining aspect of the human condition. Hunger is a primary mode of being, and it is correlated with a wide-ranging spectrum of pleasures. Yet hunger cannot be equated with pleasure, for at least two reasons. First, hunger is deeply entangled in our relationship to what is not us, while pleasure is not. Second, hunger is part of the lives of those that may not feel pleasure or may do so in a far different manner, such as early-stage fetuses or humans in a vegetative state. In this

sense, one could contend that hunger is more fundamental than pleasure for the human condition. The second section approaches hunger in its relation to the study of malnutrition, undernutrition, and famine. Here we encounter philosophical questions pertaining to the ethics and politics of food access and dieting, which are at play in humanitarian efforts, theoretical psychology, and clinical practice. Finally, the third section studies the relevance of hunger to the aesthetic value of a dining experience. To dine and to drink ultimately mean to *consume*, and the practice of consuming foods and beverages ultimately rests on our hunger. Pleasure from the palate is an activity that acquires meaningfulness in dialogue with hunger. In this perspective, food aesthetics is a discipline centered on the body of the consumer, on a dialogue between hunger and consumption experiences.

Introduction

Hunting, or the pursuit with the intention to kill wild, nonhuman animals, is one of the oldest means of human subsistence – in fact many have theorized that the adoption of hunting by early hominids may have been an important catalyst in human evolution. It is also, particularly in the case of its more modern manifestations, one of the most controversial.

For its critics, hunting inflicts unnecessary suffering upon other nonhuman sentient animals and violates their rights for ends (i.e., human subsistence and nutrition) that could be achieved by far less violent and more benign means (i.e., plant agriculture). In fact many critics charge that hunting has no ethically redeeming qualities and is motivated solely by the thrill of the kill and a sadistic delight in inflicting pain and suffering upon living creatures, with one critic, Joseph Wood Krutch, going so far as to declare hunting is “the perfect type of that pure evil for which metaphysicians have sometimes sought” (Quoted in Cartmill 1993, p. 228).

Defenders of hunting, on the other hand, contest the assertion that hunting necessarily involves greater animal suffering than other forms of subsistence and suggest that, in fact, it may involve considerably less. Moreover, they argue that the application of rights-based ethics to the biological realm ends up distorting humans’ relationship to wild nature and may constitute a condemnation of nature. Finally advocates of hunting suggest that hunting, far from being motivated by a hatred of wild nature and need to dominate it, can actually be motivated by a desire to reconnect with and affirm wild beings and natural processes.

Acknowledging that hunting is a multifaceted phenomenon involving a number of different practices, problematics, and controversies – far beyond the limited scope of an encyclopedia entry to tackle with in-depth – this essay will focus on, perhaps, the most obvious and apparent issues and questions involved in the hunting debate which center around the issues of animal welfare, animal rights, and finally the moral character of the hunter.

Hunting and the Question of Animal Suffering

Many arguments against hunting derive their theoretical inspiration from Peter Singer’s utilitarian argument for the ethical obligation for humans to be vegetarians. According to utilitarianism, the ethical rightness or wrongness of a particular course of action or policy adopted is to be judged in terms of whether the consequences of such action or policy result in the production of the greatest amount of happiness or pleasure and the least amount of pain and suffering possible for all interested parties concerned, and, in animal rights/liberation circles, Singer’s claim to fame rests upon extending this utilitarian logic to include the ethical status of nonhuman animals. For Singer argues that given the profound amount of animal pain and suffering involved in contemporary industrial meat practices, morally conscious human individuals have a duty to seek out food choices that involve less sentient animal suffering, such as a more plant-based diet. For while Singer does not deny that there are means of raising and slaughtering animals for meat that avoid the infliction of pain, such practices, he argues, are uncommon and thus the ethically prudent action is to avoid meat eating altogether and adopt a vegetarian diet whereby one is assured that the degree of animal suffering is minimized.

Though Singer himself rarely specifically mentions hunting, in the odd passage where he does, he appears to think a condemnation of hunting is implied by his wider utilitarian critique of the ethics of meat eating. In *Practical Ethics*, for instance, after discussing meat eating, he quickly dispenses with hunting in a mere sentence asking his reader to merely “apply the appropriate ethical principles” (Singer 1993, p. 68). In other words, he appears to see his utilitarian argument against the meat eating as being an unproblematic argument against hunting as well.

Nevertheless, several thinkers have argued for the ethical legitimacy of hunting precisely upon the basis of Singer’s utilitarian logic. Gary Varner (1995), for instance, has defended therapeutic hunting (or hunting employed to maintain the aggregate welfare of an ecosystem and targeted species populations) upon utilitarian grounds.

Noting that in the absence of natural predators, prey populations will quickly expand past the carrying capacity of their environment, Varner argues that therapeutic hunting may be necessary to keep such species within the carrying capacity of their environment and thereby avoid the tremendous amount of animal suffering that would be incurred by starvation. Anti-hunting theorists, such as Kretz (2010) and Mallory (2001), however, have legitimately pointed out that the absence of natural predatory populations is in no small part due to the power of the hunter lobby. Nevertheless, Varner has argued that given the present circumstances, limited therapeutic hunting is necessary in order to maintain ecosystemic balance.

Similarly and perhaps more problematically to Singer, given his vegetarian commitments, Archer (Archer 2011) and Cahoone (2009) have cogently argued that industrial plant agriculture and consequently a vegetarian diet may involve significantly more animal suffering than either the industrial meat industry or hunting. For while Singer seems to assume that plant agriculture involves less animal or sentient suffering due to the fact that plants are non-sentient and therefore feel no pain, this ignores the considerable indirect suffering to animals caused by industrial plant agriculture. As Cahoone notes, plant agriculture indirectly affects the well-being of nonhuman wild animals in several ways: (1) it involves the portioning of an area of wild ecosystems for the exclusive use by humans, thereby directly affecting the sustainability of wild populations; (2) it frequently involves killing wild populations who opportunistically feed on agricultural land; (3) it harms wild populations through pesticides, fertilizers, and other support technologies; and (4) the groundbreaking and harvesting machinery involved in industrial plant agriculture kill and maim numerous ground-dwelling amphibians, birds, and small and immature mammals (Cahoone 2009, p. 79). Archer, for instance, has conservatively estimated that a vegetarian diet results in 25 times more animals killed per kilo of useable protein than other forms of subsistence such as free-range cattle and wild-harvested or hunted game (Archer 2011, p. 979).

Indeed, particularly in the case of the hunting of wild game, there appears to be no contest. For most contemporary hunting, Cahoone argues, involves sneaking up beyond the formidable sensory array of the game and delivering a kill-shot in which death is almost instant with little risk of suffering involved (Cahoone 2009, p. 73). Critics such as Evelyn Pluhar however point out that there is considerable risk with all hunting that the animal's death will not be instantaneous and can result in crippling and injury to the prey. She also notes hunting has resulted in considerable transformation of wild habitats through brush clearance and damming (Pluhar 1991, p. 121). Nonetheless, as Cahoone notes, crippling and maiming of sentient beings also occur during the process of plowing and harvesting involved in plant agriculture (though as yet no meaningful statistical correlation has been made between the two), and in terms of the transformations of wild environments, it would appear that there is no contest.

Of course, it is possible that other scholars could weight and calculate the pain and suffering caused by plant agriculture and hunting differently and come up with perhaps significantly different numbers than Cahoone or Archer. Nevertheless, Cahoone and Archer's objections not only challenge the assumption that a plant-based diet necessarily involves less suffering than other forms of food procurement but also points to a significant weakness of utilitarian types of ethical reasoning, in that how one calculates the balance of pleasure and pain is inherently tied to which empirical factors one sees as relevant and the quantifiable values one assigns them. Thus, utilitarian calculation can frequently be used to justify two completely contradictory positions depending upon the scope and multiplicity of empirical elements or factors one considers germane to one's case and how one assesses the particular degree of pain and pleasure derived from these factors. This shortcoming of Singer's utilitarian approach has led many critics of hunting to embrace Tom Regan's rights-based approach.

Hunting and the Question of Animal Rights

In *The Case for Animal Rights*, Regan has argued that certain nonhuman animals have intrinsic rights derived from the Kantian theory of inherent rights. Though he notes the Kantian theory of rights necessarily involves the issue of rational agency, Regan extends Kant's criteria to include all those who might be interested in the maintenance of their life (i.e., animals capable of conscious awareness). In Regan's view this means that animals possessing consciousness have the basic right never to be treated as merely a means for the ends of others. Regan sees this as entailing the right to life and the right to be treated with respect which includes the right not to be harmed. Regan, however, does not believe that this right is absolute and acknowledges that there are times when in respecting someone's right not to be harmed, another's right to be harmed must be overridden. Nevertheless, he is concerned to minimize such exceptions, arguing that in these situations one must employ the miniride principle (minimize overriding) and the worse off principle. In general he sees the ascription to animals of the right to be treated with respect as entailing the abolition of raising and using animals for meat, the end of animal experimentation, and the outlawing of trapping and hunting. Indeed, Regan sees his rights-based approach as closing certain loopholes which might be permitted under Singer's utilitarian approach. For in granting nonhuman animals' certain unalienable rights, Regan argues, he is able to provide uncompromising grounds by which to condemn all forms of animal abuse such as hunting.

Certainly, it is not entirely clear how his rights-based position is not as vulnerable to Archer and Cahoon's objection as Singer's is: after all given the enormous amount of animal death and suffering involved in plant agriculture, surely plant agriculture involves the same if not a greater degree of infringement upon the rights of animals as other forms of food procurement. Yet perhaps more philosophically significant, as many environmental philosophers have pointed out, Regan's rights-based approach seems to run completely

counter to all biological and ecological reality and processes. As Ann Causey straightforwardly observes "There is no evidence that nature has assigned rights to any creatures and plenty of logical, biological and evolutionary evidence that she has not" (Causey 1989, p. 335): quite simply in the natural world not only is there no right to life but more importantly nature itself is structured according to the trophic cycle by which energy is recycled throughout the ecosystem via the consumption of organism by other organisms. To put it bluntly, life feeds on life.

This was the argument underlying the schism between animal rights theorists and environmental philosophers: with environmental theorists such as Callicott (1980) and Rolston (1984, 1988), who argued that animal rights theories were incompatible with the aims of ecological protection. The continued survival of wild ecosystems, they argue, is dependent not on the survival of the individual organism but the ecological systems of relations which sustain them. Thus, in the place of individualistic right-based theory, they proposed an ecological ethic in which the overall ecosystem and the ecological roles a species occupies in the ecosystem are more valuable than the individual members. Consequently according to this ethic, an act which may be harmful to an individual animal can be seen as valuable according to this ecological ethic if it benefits the ecosystem as a whole. This led certain environmental philosophers such as Rolston to argue for the moral legitimacy of hunting. For while acknowledging that in terms of human social morality, hunting would be considered immoral, this social morality, he argued, is inappropriate or the wrong ethics to apply in terms of our relationship with wild nonhuman animals. Rather because hunting is continuous with the ecological process of nonhuman predation and humans' original ecological niche, the appropriate ethical code to employ, he argues, is an ecological one that aims at the preservation of ecosystemic integrity. Similarly, Ned Hettinger has expanded on Rolston's argument in his seminal paper, "Bambi Lovers versus Tree Huggers," and asked whether animal rights theorists can condemn all forms of hunting and not by the same token condemn the

natural world in general and predators in particular (Hettinger 1994).

Generally, animal rights/liberation theorists have responded to this challenge by noting that it is dependent upon the naturalistic fallacy which attempts to derive ethical norms from natural ones and they point out that there are numerous examples of behavior among nonhuman animal species, such as coprophagia, brood parasitism, post-cotial mate cannibalism, etc., which are in stark contradiction to human morality (Mallory 2001; Luke 1997; Regan 2004; Evertt 2004). Similarly Singer, for instance, has famously written:

It is odd how humans, who consider themselves so far above animals, will...use an argument that implies we ought to look to other animals for moral inspiration and guidance! The point is that other animals are not capable of considering other alternatives, or of reflecting morally on the rights or wrongs of killing for food; they just do it. We may regret the way the world is, but it makes no sense to hold nonhuman animals morally responsible or culpable for what they do. (Singer 2002, pp. 224–225)

Yet, leaving aside the question whether predators cannot be considered morally culpable these responses, quite frankly, seems to miss Hettinger and other environmentalists' point, which is not that environmental entities and processes conform to human ethics but rather that if one is to articulate an ethical value for natural entities and processes, one needs to understand and appreciate wild nature as it is in and of itself, not impose human norms upon a realm whose processes appear to be antithetical to these norms in general. Quite simply, as Hettinger and Rolston point out, much of the animal liberationist/welfare discourse appears to establish the foundation of our ethical responsibility to nonhuman nature on grounds clearly antithetical to it. Furthermore, with Luke and Pluhar's condemnation of hunting as an atavistic return to nature that "would enact bashing other human beings over the skull" (Pluhar 1991, p. 124), it appears that their difficulty with hunting is not that it removes us from nature but rather that it brings us far too closely in contact with it – for the hunter is a human who kills other animals like an animal and therefore is little better than an animal. This touches upon deep ethical issues at play not only in vegetarian condemnations of

hunting but also its wider condemnation in the general population as well. For opinion poll surveys suggest that while most have little problem with hunting per se – particularly if it is done for the purposes of subsistence or ecological control – they do have a problem with the hunter, particularly the sport hunter, and specifically his or her motives, in that it is felt that the sport hunter must be informed by the most bestial (animal-like) of motives.

Hunting and the Question of Human Brutality

Eric Zencey recounts a telling anecdote whereby the vice-president of a local college informed him that it was immoral for a person to go hunting if they could buy meat (Zencey 1987, p. 60). For as Matt Cartmill has written, "Even the most enthusiastic lover of fried chicken may suspect that there is something wrong with a man who finds recreation in wringing the necks of chickens" (Cartmill 1993, p. 241). Indeed as Cartmill further goes on to write "For most of us, ceremonial going into the woods once a year with a rifle sounds about as attractive as marching into a dairy barn once a year to bash cows with a sledgehammer" (Cartmill 1993, p. 228) and just about as easy. Given then that sport hunting appears to be such an easy and straightforward affair in which success is almost guaranteed, there seems little reason to undertake it, aside from the desire to dominate, inflict pain, and kill another living creature. Little wonder then that the practice of sport hunting is popularly equated with everything from serial killing to violent rape or that anti-hunting theorists have attempted to tie hunting with every historically pernicious social practice from hierarchy to patriarchy, for it seems an easy and straightforward case of the need of the strong to assert control and dominance over the weak.

Many ecofeminists such as Marti Kheel, for instance, have argued that hunting manifests an objectivizing gaze which sees nonhuman animals as simply objects for human use and compared this to other forms of human domination (Kheel 1995). Similarly Roger J. H. King has argued that

hunting is motivated by little more than necrophilia or the love of death for death's sake and has suggested that this love of death underscores both hierarchy and patriarchy (King 1991). Mary Zeiss Stange in her book *Woman the Hunter*, however, has contested this cultural and historical link between hunting, misogyny, and hierarchy, pointing out that many hunter-gatherer societies depend on hunting as a primary means of subsistence and are some of the least hierarchical and patriarchal societies on record. Moreover, as Rod Preece has observed in his history of vegetarianism, *Sins of the Flesh*, many societies founded upon the principle of vegetarianism such as Vedic India were as extremely hierarchical and misogynistic (Preece 2008).

Furthermore, Garry Marvin has contested that hunting implicitly manifests human domination and control over the natural world by arguing that hunting differs from other forms of animal killing, precisely in terms of the absence of human control. Marvin notes that most hunting involves the killing of wild animals (which have not been genetically tamed or otherwise put under our control) and which also must be able to escape or defeat the intentions of the hunter (Marvin 2006). In fact, far from reinforcing a sense of human superiority, he points out hunting can impart in the mind of hunter a much-needed sense of human inferiority. For in many respects wild animals have physical and sensory endowments which put humans to shame; for not only are they faster and stronger but they also have a sensory acuity, particularly in terms of their sense of hearing and smell far beyond those of humans. Add to this a formidable behavioral repertoire of stealth and evasion and it is little wonder that, as Zencey points out, fewer than 10% of all hunts are successful (Zencey 1987, p. 60). Indeed, despite the common tendency, particularly among critics of hunting, to focus on the act of killing to the exclusion of all else, the actual moment of the kill represents the tiniest fraction of the time spent hunting – if it occurs at all. The vast majority of the hunt, as Cahoon notes, is spent in continual searching for signs of the prey, and, “Often this searching is hunting, is the entire experience, because most hunts are unsuccessful” (Cahoon 2009, p. 74).

This searching itself requires considerable knowledge of bush craft, the surrounding environment, and the habits, behaviors, and spoor of the prey (Cahoon 2009; Kerasote 1993; Shepard 1973; Zencey 1987). This could explain why, in demographic surveys, hunters routinely rank above other sections of the population in terms of their general knowledge of wilderness and wild species (Kellert 1978). In fact, it is the opportunity to spend time and get close to nature, rather than the need to give vent to some frenzied bloodlust, which hunters routinely invoke when asked why they hunt (Kellert 1978). Moreover, as José Ortega y Gasset notes in his phenomenological account of hunting, hunting requires an unrivaled focused attention and alertness toward one's environment and he argues that this is a fundamental aspect of its appeal (Ortega 1972).

Yet hunting stimulates in the hunter not only a hyperawareness of their surroundings but also an intense sense of intimacy between the hunter and the prey. For, as Ortega and others point out, the very activity of tracking and stalking the prey demands not that the hunter objectify the prey but requires precisely the opposite: the hunter must assume that the prey has thoughts, intentions, and is in some sense conscious (Ortega 1972; Kerasote 1993; Parker 2010; Shepard 1973; Stange 1997). Throughout the hunt, the hunter needs to continually get inside the mind of the animal, to see the world and the current situation from its perspective. Did the prey hear the rustle of grass as the hunter crept forward? Does the change in direction and speed of its tracks or the tilt of its head indicate that it has caught the hunter's scent? Thus, the hunter must constantly imagine the *subjective* state of his or her quarry, attempting to quite literally perceive the situation through its senses.

This, then, to many anti-hunting theorists is the aspect of hunting that is perhaps the most incomprehensible: how can one identify so intimately and viscerally with the mind of another animal and then take its life? Kheel, for instance, has suggested that “In order to understand how an act of identification can coexist with the desire to kill a being with whom one identifies, it is important to understand the ambivalent nature of the hunt. . . The hunter is both driven by conflicting desires to both identify

with an animal and to deny that he is an animal himself" (Kheel 1990, p. 133). Yet, many commentators have argued that one of the virtues of hunting is precisely that it confronts us with the facticity of our animality and the fact that we like all other animals are mortal and will die. Indeed they argue that vegetarianism itself is motivated by an aversion toward this acknowledgment that we are carnal, finite beings and hence mortal (Cerulli 2010; Nelson 1997; Kover 2010; Shepard 1973).

Summary

The hunting debate is in large part structured around questions of animal suffering, animal rights, the nature of nature, and ultimately the nature of our humanity. For one side, hunting is a brutal activity which imposes unnecessary suffering and contravenes the innate rights of nonhuman animals to life solely out of the human desire to inflict pain and domination upon the nonhuman world. For the other side, hunting arises out of the need to viscerally connect wild nature and wild processes. Yet whatever side of the debate one falls into, what cannot be debated is that the hunting debate ultimately involves competing visions of nature and what this implies in terms of our nature.

Introduction

In a very general sense, *hybrid* can be understood to be any organism that is the product of two (or more) organisms where each parent belongs to a different kind. For example, the offspring from two or more parent organisms, each belonging to a separate species (or genera), is called a “hybrid.” “Hybridity” refers to the phenomenal character of being a hybrid. And “hybridization” refers to both natural and artificial processes of generating hybrids. These processes include mechanisms of selective crossbreeding and cross-fertilization of parents of different species for the purpose of producing hybrid offspring. In addition to these processes, “hybridization” also refers to natural and artificial processes of whole genome duplication that result in the doubling or trebling of the sets of chromosomes of the organism.

This entry provides an overview of the impact of hybridity on agriculture. It begins with an historical sketch that traces the early horticulturalists’ and naturalists’ investigations of hybrids. This starts with the observations of Thomas Fairchild and Georges-Louis Leclerc, Comte de Buffon, and leads to the explanation of its mechanism by Gregor Mendel, James Watson and Francis Crick, and Ernst Mayr and the eventual manipulation of hybrids and hybridization by Barbara McClintock.

Following this, the reader is introduced to a number of key terms and concepts in use within current research as well as highlighting diverse ethical concerns that center on hybridization. Recent research that attempts to ascertain the role of hybridization in adaptive change will be introduced. This will include research on the evolution of crop species, increased biodiversity, and the use of hybrids to manipulate phenotypically desirable traits in agricultural crops. The focus of the discussion is on a particularly significant type

of naturally occurring hybridization, polyploidy hybridization. Polyploids are organisms which have more than two complete genomes in each cell. This kind of hybridization is ubiquitous among crop plants. The role of polyploidy in plant evolution and the affects of polyploidy on plants and animals will be reviewed. A critical discussion of its agricultural value in the production of fertile polyploid hybrids highlights key epistemological, ontological, and ethical issues. These are illuminated with reference to the distinct processes of artificial and natural hybridization.

A survey of these different kinds of hybridization includes the ethical and economic impacts of hybridity on global nutrition, the environment, and considerations of some practical implications for the agricultural industry. Tracking the role of hybrids, the process of hybridization, and the current impacts of it for agriculture requires knowledge of the history of its early conceptualization, understanding, and use. This is the topic of the following section.

Historical Background

With the domestication of plants and animals, early farmers became familiar with the practice of crossbreeding as a way to produce food crops and livestock with desirable traits. They were also aware of naturally occurring hybrids in both animals and plants. But although the phenomenon of hybridity was known, the intentional crossing of organisms was not recorded until 1717. The English horticulturalist, Thomas Fairchild, was the first to intentionally produce a hybrid by crossing a carnation (*Dianthus caryophyllus*) with a sweet william (*Dianthus barbatus*) in a small city garden in the London district of Hoxton.

In 1753, the French naturalist, Georges-Louis Leclerc, Comte de Buffon, discusses the infertility of hybrid offspring which is the result of the reproductive relationships (either through natural copulation or through artificial insemination) between two animals of different species. In *The Donkey*, he discusses the case of the mule, an infertile cross between a donkey and a horse

(Buffon 1753). In 1890, Wilhelm Rimpau was one of the first to develop an intergeneric hybrid crop with agricultural potential. This was triticale. Triticale was the result of the hybridization of wheat and rye. Together with other German breeders, Rimpau built upon this new technology and made improvements in winter and spring wheat crops.

It was not until 1900 that the underlying mechanisms responsible for hybridity (and more generally, the principles of inheritance originally discovered and published by Gregor Mendel in 1866) were widely known and understood. This came when Erich Tschermak, Hugo de Vries, and Carl Correns independently corroborated Mendel's research on the inheritance of factors in crossed hybrid generations in the common pea (*Pisum sativum*) within their own agricultural studies.

In the late 1920s, high-yield hybrid corn was developed and marketed in the United States. The discovery of the structure of DNA by Francis Crick, James Watson, Rosalind Franklin, and Maurice Wilkins in 1953, and the later development of genetics and genomics that followed, provided knowledge of the biochemical mechanisms of hybridity that would complement the practical knowledge already established in agricultural technology. In the early 1980s, the use of this practical knowledge came to fruition in its implementation within biotechnology. It was at this time that biotechnological research and agricultural practice combined in the production of a hybrid tobacco plant with antibiotic resistance in 1982. With this union of research and practice, discussion of the economic, legal, and ethical impacts with this new technology also followed apace. For instance, within the next 4 years, the subsequent Environmental Protection Agency gave approval for the antibiotic resistant tobacco in 1986. This laid a precedent for further biotechnologically produced hybrids. As a result of the research on tobacco and the approval for its sale, other biotechnologically produced hybrids such as soybeans, corn, and cotton followed. These were approved for sale shortly after (in 1995 and 1996) in the United States (Wieczorek and Wright 2012).

While early horticultural and agricultural practices took as given the importance of

hybridization for the cultivation of more desirable plant characteristics and higher-yield crops that were better adapted to diverse environmental conditions, the role of the hybrid was still being discussed as an evolutionary anomaly among many zoologists. For example, Ernst Mayr formulated his highly influential BIOLOGICAL SPECIES CONCEPT (BSC) with specific reference to the exclusion of hybrids by defining species as those populations which are reproductively isolated from other population groups (Mayr 1963). That reproduction can occur between members of different species through hybridizing was a problem for his conception of species that required a solution. Mayr's solution was to deny that hybridization between organisms of different species was evolutionarily significant. He maintained that the majority of hybrids are "totally sterile" and "successful hybridization is indeed a rare phenomenon" (Mayr 1963). Mayr concluded, on the basis of this reasoning, that since hybrids are rare, they only ever amount to "evolutionarily unimportant mistakes" (Mayr 1963). There was a striking disconnection between the theoretical discussions of hybrids as "evolutionarily unimportant mistakes" among zoologists and the practical use of hybrids by farmers and agronomists. While the former denied the evolutionary impact of hybrids, the latter not only recognized it but routinely used hybrids to improve crop performance and increase yield in cultivation.

Polyploid Hybridization

The term "polyploidy" was originally introduced in 1916 by the German botanist, Hans Winkler. Barbara McClintock's early research on *Zea mays* L. (maize) suggested that epigenetic silencing may have a particular evolutionarily important role in polyploids. The process of polyploidization contributes large-scale genomic reconfigurations and changes in gene expression and functioning. Her later research suggested that this process might be an instance of what she referred to as "genomic shock," an event that causes increased transposable element activity and epigenetic silencing (McClintock 1984).

Rather than dismissing hybrids as insignificant sterile evolutionary dead ends as Mayr did in setting out his BSC, McClintock's research focused instead on the role of hybrids and hybridization as producing novel mechanisms of evolution: "Species crosses are another potent source of genomic modification" (McClintock 1984). The shift from hybridization being understood as an occasional taxonomic nuisance, with no evolutionary impact, to a mechanism capable of large-scale genomic reconfiguration amounted to a revolution in how hybrids and the process of hybridization were viewed.

The Role of Polyploid Hybridization in Plant Evolution

Polyploidy occurs widely in angiosperms (flowering plants) and is believed to play a significant role in plant evolution (Soltis and Soltis 2009). Polyploidization is a naturally occurring mechanism that leads to instantaneous speciation. Instant speciation refers to the formation of a new species in one generation. Speciation is usually a gradual process that takes place over thousands of generations. This kind of hybridity is the result of a doubling or trebling of the sets of chromosomes of the plant and is ubiquitous in agricultural crops (Udall and Wendel 2006). The result of polyploidization is not only genome duplication but also variation in the regulation and expression of genes from the parental diploid to the polyploid progeny.

These changes may (in some cases) lead to higher fecundity, phenotypic variation, and environmental adaptedness of the polyploid. Duplication of the genome is thought to provide organisms with more resources and a potential for increased ecological flexibility. This may allow them to populate a new or extended environmental niche; have greater adaptability to stressful environments, the ability to mask recessive mutations that could have a negative impact on the organism; and possess increased vigor over diploid species. In these cases, hybridization may not be best described as a detrimental breach of species boundaries threatening species separateness (as Mayr suggests), but may instead be better understood as an evolutionary advantageous

mechanism by which an organism can increase its genetic and epigenetic resources (Kendig 2008, 2013).

Polyploidy in Agriculture

High-yield crop varieties of maize, cotton, wheat, oilseed rape (canola), peanut, and sugarcane are all the result of whole genome duplication and hybridization (Udall and Wendel 2006). These crops are allopolyploids. Allopolyploids are a type of polyploid that are defined as organisms whose cells include two or more distinct genomes that can come about through hybridization of two different species. Allopolyploids are distinguished from autopolyploids which are organisms that have genomes that are identical or very similar and arise from the same species.

Studies focusing on a variety of wild and domesticated species have shown that allopolyploids have an increased ability to respond to biotic and abiotic stress in comparison to their diploid parents (Kim and Chen 2011). While by no means conclusive for all polyploids, these kinds of evolutionary adaptability have been extensively studied in recent research on domestic cotton polyploids. Polyploid cotton has been found to produce stronger fibers than diploids. As a consequence, the polyploid cotton is often preferred to the diploid cotton and has a greater market value globally.

Understanding gene expression of these and other allopolyploids has contributed to a better understanding of the different transcriptome changes of diploids and allopolyploids that can be significant for crop production. Such research may reveal how polyploid wheat and rye resist abiotic stress or insect attack. But in order for polyploidy to be used effectively as a marker for improving crops, an understanding of its effects on the whole organism needs to be known and understood (Udall and Wendel 2006). If this were possible, patterns of gene expression that are evolutionarily changeable within allopolyploids and other polyploids could be selected for and used to produce crops with desired phenotypes such as increased stalk strength, root health, and resistance to disease or predation or increase the nutritive value of crops for humans or feed grain for livestock.

Polyploids, Homoploids, and Hybridization in Animals

Although many plant hybrids are fertile, animal hybrids are often sterile. However, the classic example of the mule as the evolutionary dead end of a hybrid cross cannot be generalized across all species. Animal hybrids usually occur by means of homoploid hybridization. Homoploid hybrids occur as a result of two organisms with the same chromosome number interbreeding. Differences in chromosome number complicate mitosis and frequently result in inviability of the hybrid animal.

Polyploid hybridization in animals is rarer but does occur and has been extensively studied in a variety of fish species, including the red crucian carp and blunt snout bream hybrids, as well as the widely studied cichlid fish species complex that exists as the result of multiple hybridization events.

A Taxonomy of Hybrids: Natural, Artificial, Induced, and Biotechnologically Produced

Polyploid hybridization can occur naturally and can also occur as the result of intentional crossing of organisms in the case of artificial selection and breeding among homoploids or polyploids. In addition to natural and artificially produced hybrids, hybridization can also occur by chemically inducing them. For instance, polyploidization can be induced in kiwifruit by means of colchicines (see Wu et al. 2012). And perhaps the most widely discussed within the bioethics literature, hybrids, can also be produced by means of biotechnological interventions to produce transgenic hybrids between diverse taxa. The focus of the remainder of this entry will be on these naturally and biotechnologically produced hybrids and their ethical impacts.

Ontological, Ethical, and Legal Impacts of Hybridity in Agriculture

Ontological and Ethical Distinctions: Natural and Artificial Hybridizing

Natural hybridization is often contrasted with *artificial* hybridization. However, natural hybridization is the occurrence of hybrids without intervention of any kind. Artificial hybridization

is used in all conventional, traditional, and organic farming that relies on artificial or selective breeding. Artificial hybridization is also used in biotechnologically produced hybridizing. “Natural” and “organic” may more particularly impute the nonuse of certain types of farming techniques, namely, biotechnologically assisted farming techniques, variously referred to as genetically modified organisms (GMOs). These crops are the result of altering an organism’s genes by direct removal or insertion of DNA from another organism or DNA. It is a type of artificial hybridizing which occurs in the lab rather than in the field. This differs from traditional artificial breeding methods in that the organism is modified by directly making changes to the DNA to produce different phenotypes rather than breeding hybrid crosses of parents with desirable phenotypic characteristics.

Non-GMO Farming and Organic Farming

Non-GMO farming and organic farming may trade on the ideal of natural production as a contrast class to the artificiality or engineered variety, but all farming involves artificial selection, and some organic farming may allow biotech tweaks but not GMOs. This demarcational fuzziness means that what kind a thing is (GMO or non-GMO, naturally or artificially produced), and therefore to what ontological category it belongs, becomes difficult, if not impossible, to adjudicate. This ontological fuzziness also has impacts on ownership and distribution and has myriad ethical ramifications.

Biotechnologically produced hybrid crops bring with them a host of legal issues including liability and intellectual property issues. Liability for GMO contamination has been discussed with regard to cross-hybridization especially in the production of soybeans, cotton, oilseed rape, and maize. Conventional farmers, whose crops have been compromised due to pollen drift (cross-pollination with transgenic crops), can be sued for patent infringement if they keep their seeds and replant them even if they did not know that these seeds are the product of an unintentional transgenic cross. Conventional farmers without a license to use the transgenic seeds can be prosecuted for using their traditional methods of seed

saving, sharing, and exchanging and planting them the next year (McEowen 2004).

Biotechnologically Produced Hybrid Crops (Conceived of as a Solution to Drought and Hunger)

Biotechnologically produced hybrids have been discussed as a solution to growing drought and the effects of climate change on agriculture in developing and industrialized countries as well as a solution for global hunger and malnutrition. Interest in these technologies as solutions to improve global health was expressed early on by the director general of the United Nations Food and Agriculture Organization, Jacques Diouf (2001). In a press release, Diouf stated that the use of biotechnologically produced hybrids and GMOs must be considered as a possible solution to “the supply, diversity, and quality of food products and [a way to] reduce costs of production and environmental degradation, as the world still grapples with the scourge of hunger and malnutrition” (Diouf 2001). Diouf maintained that the nutritional needs of the world have outstripped the capacity of conventional farming techniques. In order to feed the world’s population, biotechnological means of increasing yield and nutritional value of crops must be seriously considered.

Many biotechnologically produced crops currently on the market are designed to withstand herbicides used to control weeds such as water hemp, ragweed, and Palmer amaranth pigweed (e.g., IMI corn, STS soybeans, Roundup Ready soybeans, canola/rapeseed, cotton). One of the most widely discussed are crops that have been created that are tolerant to HPPD inhibitor herbicides widely used in corn production (Successful Farming 2012). Farmers growing herbicide-tolerant crops can limit the amount of money spent on controlling weeds (Successful Farming 2012). Growing these herbicide-tolerant crops also allows the farmer multiple modes of action to control a variety of weeds while not harming the yield of his or her crop.

In addition to herbicide tolerance, agricultural companies are currently producing hybrids that solve problems of extremes of temperatures (e.g., extreme heat), drought conditions/flooding, water

shortages (due to the rapid reduction of aquifers or other controversial irrigation techniques), low pollinator populations (e.g., bees), and lower yields that affect crops in the many of the western seed-crop states in the United States (Kansas, Missouri, Colorado, Nebraska, Oklahoma, Texas, South Dakota) (Minford 2012). To do this, seed companies isolate genes identified with controlling how plants react to stress. Some rely on selecting genetic markers to cross with desirable phenotypes, while others rely on single-gene biotechnological approaches to add corn drought-tolerant genes from bacteria to produce drought resistance transgenically (Minford 2012).

Biotechnologically produced crops have also been engineered to be resistant to insect predation. For instance, the transgenic cotton *Bacillus thuringiensis*-cotton (Bt-cotton) and Bt-maize are both bred to diminish the effects of certain pests. *B. thuringiensis* is a gram-positive soil-dwelling bacterium. Bt-cotton and Bt-maize are produced with a toxin of *B. thuringiensis* which is toxic to many species of lepidopteran larvae (caterpillars) that feed on the stalks, ears, and leaves and the coleopteran larvae (beetle grubs) that feed on the roots of cotton and maize plants (Thalmann and K  ng 2000).

One of the frequently discussed benefits of Bt-maize and Bt-cotton is that farmers can reduce their reliance on airborne insecticides. This impacts not only the air quality but also soil and the environmental impact of these chemicals on nontarget crops and wildlife. It also provides an advantage to the farmer in terms of limiting exposure to these chemicals. The farmer can reduce his or her direct contact with the chemicals which may positively affect the health of the farmer. Planting weed- and insect-resistant crops also reduces the farmer's time in the field and expenditures on chemical herbicides, insecticides, and fungicides.

Biotechnologically engineered ways of increasing the nutritive value not only for human consumption but also for use in animal feed have also been explored. In the United States and EU, more than 60% of corn and soybeans are used to feed livestock with corn being the major feed source in a wide variety of animals including

poultry, swine, and dairy cattle (Thalmann and K  ng 2000). New transgenic hybrids increase desirable nutrients in crops fed to livestock. As a result this leads to healthier more productive livestock and potentially a lower feed bill if the farmer does not need to buy additional minerals to add to feed. For instance, crops of seed or grain can be altered to produce a more desirable composition in recombinant plants which can produce higher levels of oleochemicals, proteins, or carbohydrates (Thalmann and K  ng 2000). Some hybrids are also designed to remove things in the crop that are harmful to animals. For instance, canola is a modification of rape that reduces the uric acid within the plant which is toxic to livestock. This means that the crop can be used as a feed crop instead of just as an oilseed crop. There is a hybrid of fescue for hay that also reduces its toxicity to cattle.

Biotechnologically Produced Hybrid Crops (Conceived of as a Threat)

In addition to discussions of the benefits of biotechnologically produced hybrids, there have also been considerable ethical concerns raised about the threats the production of biotechnological hybrids poses to public health and the environment. With regard to public health, these have focused on the potential of transgenic crops for carrying antibiotic resistance that would compromise drugs currently in use to treat illnesses.

With regard to the environment, ethical discussion has focused on the potential destabilization of ecosystem balances with the introduction of herbicide resistance and insect resistant crops. With reference to socioeconomic issues, these worries have focused on the labeling and marketability of organic products. One ethical and economic concern is that products may be accidentally contaminated by means of cross-pollination from neighboring transgenic species. This would affect farmers' ability to accurately maintain organic crops due to transgenic crop drift from other non-organic farms.

In addition to these concerns for organic food production, other worries focus on the impact of

transgenic crop drift on conventional farmers who practice seed saving, sharing, and exchanging. Some recent research suggests that saving seeds from plants that produce desirable traits to plant in the following year (to ensure that they had better crops) has been a traditional practice that has a history that goes back to that of the early Neolithic farmers (Shillito 2011) and continues to be a practice of traditional farmers in developing countries and socioeconomically vulnerable communities. The suggestion that the practice of seed saving, sharing, and exchanging should be curtailed to protect crops has been mooted. However, restrictions on these practices would disproportionately affect these cohorts and possibly frustrate the social and economic inequities already present. A move that itself would involve multiple ethical repercussions.

The prime ethical concern with regard to transgenic hybrid crops is the inadvertent dispersal of the transgenic crop pollen through wind or the movement of pollinating insects. The dispersal of herbicide-tolerant crops to other conventionally farmed fields is of special concern as their dispersal could produce *superweeds* that would not be controlled by herbicides currently in use. In addition to concerns about the possible creation of superweeds, analogous problems may arise with regard to insects which are the focus of insecticide-resistant crops. The incidence of potential *superpests*, produced as a consequence of adaptive resistance to targeted insecticide resistant crops, has also been observed and discussed (Liu et al. 1999). Concerns have also been raised about the possibility that crops bred for resistance to some pests may actually encourage the proliferation of other pest insects creating populations of secondary pests. If the primary insect predators are reduced, other secondary pests such as the boll weevil and stink bug may rebound (Liu et al. 1999). In addition to these worries, insect-resistant crops such as Bt-cotton and Bt-maize may also affect nontarget species of insects such as green lacewings and other insects that are beneficial to crops. The introduction of herbicides and insecticides may have the potential to disrupt agricultural production as well as natural ecosystems in unpredictable and potentially catastrophic

ways. These secondary effects would raise significant concerns for agro-industry, environmentalists, and conservationists alike.

Industry-Based Initiatives

Much of the recent ethical discussion has focused on the impacts of introducing new transgenes into the environment and their effect on production and yield. However, the performance of different crops is the consequence of multiple variables which include but are not limited to average rainfall, irrigation, drainage, nutrient content and composition of soil, drought, wind, insect control, weed management, choice of pesticides (herbicides, insecticides, fungicides, etc.), existence of hedgerows or borders, local biodiversity, crop rotation practices, and harvesting times.

Industry-based actions to curtail cross-hybridization between commercial crops using biotechnologically produced hybrids and to protect the interests of traditional and organic farmers have grown in recent years. The group, Save Our Crops Coalition, aims at curtailing the inadvertent application of synthetic chemicals or fertilizers to organic crops or the inadvertent spread of these to traditionally grown crops. Other initiatives based in industry and cited in trade journals are to not to overuse one pesticide chemical (strongly discouraging a one-size-fits-all approach to weed management) and instead suggest that farmers identify weeds and adjust their control to the specific needs of their particular crops (Successful Farming 2012). Targeting the herbicide to the weed rather than overusing the same herbicide has been an increasingly adopted practice since the discovery of the resistance to herbicides of the group triazine of more than 55 different weeds (Thalmann and K  ng 2000).

Trade journals and the experience of individual farmers suggest that there are other impacts that farmers need to be aware of with regard to the management of hybrid crops. Increases in yield and desirable plant phenotypes such as stronger stalks and resistance to drought, pests, and herbicides used to control weeds have other impacts that affect practical crop management. Some

hybrid plants have stronger stalks and have more biomass and plant residues than do traditionally produced crops. Others are bred to have less biomass and send more energy to the grain head. Because of this, hybrid plants also impact farmers' choices in buying equipment essential to harvesting and tillage. Some hybrid crops require more horsepower and torque from farm machinery to manage plant residue after harvest and remove crops during harvesting and by tillage equipment.

Farmers are aware of the mutability of crops due to accidental cross-pollination which can lead to the spreading of a particular undesirable trait throughout multiple hybrids. Practical measures to guard against this include increasing the biodiversity of crops planted in fields and ensuring that different kinds of crops are planted in the same field at different times of the year. This latter practice is called *crop rotation*. Rotating crops in the same field reduces the potential degradation of the soil. By alternating crops, the nutrient composition of the soil can be maintained or improved. Crop rotation also limits the population of crop-specific diseases and insect pests and potentially reduces the number of superpests that may develop.

In addition to these considerations, trade journals have also expressed concern over the use of old herbicides with new transgenic crops. The continued use of old herbicides in an industry with new biotechnological solutions appears to some as incongruous. These herbicides are being used, in part, because of the limits on research, testing, and introducing new chemicals into crop production (Successful Farming 2012).

Current discussion reflects the confluence of three different modes of investigation: (1) How research and biotechnology can provide new ways of understanding the mechanisms of hybridization, (2) how these mechanisms can be used in practice to increase agricultural production, and (3) how we *should* use these new technologies. The latter ethical question requires that biotechnological research and agricultural practice link up in ways that are reciprocally informative. That is, finding an ethical route to maintain sustainable agriculture using hybrids in agriculture depends not just on research methodologies and

biotechnological strategies of increased production but also on the business of being a farmer.

Summary

The interplay between the theoretical understanding and the practical knowledge in agriculture has been both complimentary and adversarial in the understanding and use of hybrids in agriculture. The benefits and potential risks to the environment, the agriculture industry, worldwide food crop production, and global socioeconomics are just some of the ethical issues that have arisen with the use of hybrids in agriculture. An understanding of the biotechnology currently in use as well as the history of research on hybrids beginning with Fairchild, Buffon, Mendel, Mayr, and McClintock has been provided in this entry. This, combined with a survey of industry management strategies, international discussion of the use of biotechnologically produced hybrids, as well as farmer-led concerns with unintended cross-pollination fills out a picture of the role of hybridity in agriculture. Key cases for ethical discussion include polyploidy hybrid use in agriculture, herbicide-resistant crops, and insect-resistant crops such as Bt-cotton and Bt-maize. Ethical discussions have also centered on the practice and restriction of seed procurement, distribution systems, biotechnology development, and the effects of the use of hybrid organisms on both traditional agricultural farmers. Concerns over the potential for unintended negative effects such as the development of superpests and superweeds have also been discussed. These have wide-ranging consequences that affect both the general public and the environment. Approaches intending to address the multiple aspects of the use of hybrids in agriculture in ways that are ethically responsive to concerns of all cohorts have been reviewed. These have arisen from the agricultural industry itself, trade journals, coalitions of farmers and the public, biotech companies, and the United Nations FAO. These suggest that to be successful, any integrated ethical approach must be mindful of a range of agricultural practices, communities, and future impacts.

Introduction

In this exploration of the relationship between agriculture and immigration, we seek a history beyond one merely of general population movements or of agriculture as an ecological mode of living. The focus is on the various kinds of relationships the two human endeavors have with one another.

While people have long moved from one place to another in order to grow subsistence crops, based on seasonal, topographical, or some other factors, and while immigration is perhaps as often a result of the termination of agricultural activities, we will focus on transnational migration that entails the engagement in agricultural pursuits on “foreign” land, either voluntarily, inadvertently, or involuntarily, in the context of contemporary late capitalist, globalized agriculture.

The Nature and Evolution of the Relationship Between Agriculture and Immigration

Agriculture is a mode of living independently invented or adopted by various cultures or civilizations around the world and over time. It has often resulted from migration and the eventual settlement of large groups of perhaps once more migratory people who, for one reason or another, sought to pursue agriculture in an adopted land. We can speak of agriculture in Western Europe, for example, and debate the evidence as to whether it was the result of cultural diffusion or independent invention. Rowley-Conwy (2011) argues that agriculture was introduced by migrants from Central Europe as they moved toward the Atlantic. He concludes that much of the major spreads of agriculture in Northern and Western Europe were achieved vis-à-vis the immigration of a considerable proportion of farmers. Along with Rowley-Conwy, many scholars now focus on migrationism as opposed to indigenist origins of agriculture—that agriculture, in this case, was carried into Europe by Indo-European speakers as opposed to the idea that agriculture was adopted by local hunter-gatherers.

In such cases, migration and agriculture are presumed to be deeply intertwined. A similar scenario might be appropriate to describe the agricultural origins of Southeastern Europe. Yet the point here is that immigration has long been a source of agricultural development in general. Migrants considered ethnic Greek and determined to be refugees in need of repatriation from the crumbling Ottoman Empire by the terms of the Treaty of Lausanne in 1924 significantly rejuvenated agriculture in Greece at that time (Voutira 2007). Agriculture and immigration have become even more intertwined with each other as we move toward the contemporary period of increased migration across nation-state borders and industrial-scale agriculture in need of cheap foreign labor.

15.3% of all White male farm operators (2,100,000) in the USA in 1900 were foreign-born (Cance 1925). Twenty-seven percent were either foreign-born or of foreign parentage – of primarily Canadian, English, Irish, Scotch, Welsh, German, Swedish, Norwegian, Danish, Swiss, Italian, Polish, Dutch, Portuguese, and French descent. There were also Russians, Austrians, Romanians, Greeks, Finns, as well as “Orientals.” Two percent of farmworkers were Mexicans in 1900, as compared to the very high percentage of Mexican immigrant farmworkers in the USA today whom we are consequently forced to consider in some more depth. Indeed, the number of Mexican migrant laborers in the USA has steadily risen since then. Eighty-nine thousand Mexicans were admitted to the USA in 1924. There were estimates of 250,000 illegal Mexican immigrants annually entering the country around that time (Cance). They came to New England to pick cranberries and Texas to pick cotton and later primarily to California in order to weed beets, among numerous other agricultural tasks. There were no immigrant quotas at that time and, what is more, quotas have become largely irrelevant with the advent of large-scale illegal immigration.

We can trace a similar immigrant and agricultural history in Canada, where Chinese, Japanese, Doukhobor, and Portuguese men were the first migrant farmworkers. This immigrant influx has evolved to the point where, in 2003, 98% of

British Columbia's 6000 farmworkers were South Asian immigrant women. In 2008, due to new access to the Canadian Federal SAWP (Seasonal Agricultural Worker Program), almost 3000 predominantly male Mexican farmworkers came to British Columbia.

In most cases, power relations between geographic areas and political entities play a considerable role. General colonial patterns which emerged as Europe spread its political and economic control outward remain across the world, as in the Algerian migratory pattern of entering France (its former colonizer) so as to then gain entry into Italy and supply the need for cheap agricultural labor there. The European Union has worked to open North African markets to its subsidized wheat as well as to keep North African fruits and vegetables out of the EU market. In much the same way that the USA has dealt with Mexico, these more powerful political entities manipulate agricultural markets in part to supply their farmers with migrants "willing" to cross the border to work, with all the risks doing so entails (Cole and Booth 2007, p. 100).

While the primary concern here is to identify themes and document scholarship regarding immigrant participation in agriculture on contemporary "foreign" land, there are other ways to conceptualize the nature of the relationship between immigrants and agriculture, in other times and places, that should be mentioned. Notably, we could discuss the prevalence of out-migration from primarily agricultural to industrial economies, for example, and the consequent termination of some agricultural production as a result. Migrants left Greece en masse after independence from the Ottoman Empire to the Empire's merchant cities in the early to mid-nineteenth century, to primarily Egypt and the USA beginning in the 1890s, and then also to other industrialized places that were relatively accepting of immigrants, such as Australia, North-western Europe, and Canada. Chain migrations ensued and continue to the point where Greece is hard to identify as primarily either an agricultural or industrialized country. Much of rural Greece has become extremely depopulated. Waves of emigration from primarily agrarian Greece have

slowed considerably in the last quarter of the twentieth century, and agriculture has recently become rejuvenated to some extent but only with the support of immigrant (primarily Albanian) labor. This brings us back to the focus in migrant participation in agricultural work.

The Contemporary Relationship Between Agriculture and Immigration

Agriculture entails the practices of farmers, cultivators, agrarians, and perhaps others (such as the political class of "peasants" whose identity references power relations between people over agricultural land and produce). Notable are the movements of people for particularly agricultural purposes; swidden (slash and burn) or seasonal agriculture often demands a certain migration of participants – in order to find/create nutrient-rich soil or proper growing temperatures, for example. Yet migrations are often more forced. The need British mills had for sheep wool and new British urbanites had for beef pushed small-scale subsistence farmers off their land in the eighteenth and nineteenth centuries (Barfield 1998).

Today, in so-called developed countries, or in the countries of the "global north," agriculture largely entails the labor of migrant farmworkers. With the onset of modern industrialization and urbanization, the advent of time- and labor-saving farm equipment, as well as the modern stigmas associated with agriculture as a "backward" way of life that have consequently taken root in many places around the modernizing world, migrant farmworkers have been coming and going in increasing frequency, leaving farmwork in search of wages or a better life as well as leaving to find agricultural work in agricultural spaces abroad that have been abandoned by the local population. Forced or otherwise encouraged, immigrant farmworkers continue to come in the form of seasonal and cheap labor and go, seasonally for the most part, often also in the form of some kind of remittance sent back home.

Of course there are many specific push and pull factors to take into account in the age of contemporary agriculture. In any case, in over

10,000-year-old history of human involvement in agricultural pursuits, immigrant farmworkers have now become a significant late or postmodern component of the globalized agrarian world. Agriculture and immigration come together as specific economic, political, and otherwise social and cultural movements today. Of the myriad and often hidden ways in which people now become engaged in this work, there are basic academic points to make which reflect the large-scale, “fast” capitalist, and globalized nature of agriculture.

Beyond the fact that agriculture is often a direct result of immigration (as in the migrationist theories regarding the development of agriculture as a mode of living in Western Europe), immigration can deeply affect what agriculture ends up looking like, influencing crop selection and investment decisions (Cole and Booth, p. 69) as well as political opinions and legal structures. In Catalonia and Andalusia, Spain, for example, farmers have shifted from cereal crops to labor-intensive fruit tree and greenhouse cultivations as a direct result of access to migrant laborers from Asia and North Africa. Migrants typically work harvesting somewhat delicate crops that cannot be harvested easily by machines. Tomatoes, strawberries, and flowers are some of the most notorious crops requiring this handwork. Greenhouse operations, which can make for quite difficult working conditions and are often year-round, also typically require migrant work. Greenhouse operations may thus provide a somewhat more stable form of migrant employment that can be seen to encourage more permanent settlement.

Migrants facilitate other domains of the agricultural sector as well. They became a significant factor in what is known as the “broiler” industry in the Southern USA beginning in the 1980s. Hispanics and Asians, primarily, took positions left by some African Americans who were able to move out of slaughterhouses. The Vietnam War had earlier siphoned off some American men, creating the need for cheap manual labor as the industry also expanded (Constance 2008). Hierarchies typical of slaughterhouses – each position serving to reinforce the other vis-à-vis fear and intimidation – make this kind of work even more difficult than it already would be and serve to

maintain an overall exploitative structure. Race, ethnicity, language, and other forms of categorization typically pitch immigrants in competition with each other to the benefit of employers. Scholars consider these slaughterhouses representative of a classic agricultural model based on decentralized production, informalized labor, and global sourcing – an organizational archetype (Constance, p. 27) in which capital thrives on uneven global development.

The relatively poorer countries of Europe, often referred to collectively as the “PIGS,” Portugal, Italy, Greece, and Spain, have long modern histories of massive emigration from agrarian poverty. Yet they have now become countries of immigration largely due to their entry into the EU. Italy, once a supplier of labor to the USA, now receives its own mass of migrants from Tunisia, Bangladesh, the Philippines, Nigeria, and Sri Lanka. In such places, we can see a relatively clear picture of late modern migrations in and out of agriculture that we have begun to describe. A lack of industrial development in many parts in these countries, despite their inclusion in the EU, results in a reliance on agriculture. The unwillingness of the local population in Greece, for example, to continue to engage in agriculture – the local poor, students, and housewives who used to make themselves available for seasonal work harvesting grapes or olives – now outsources this to Albanians and more recently to Middle Eastern or African migrants in favor of other kinds of less arduous or less stigmatized and better paid “first world” wage work if and when they need it.

Overall, scholarly social science on the contemporary relationships between agriculture and immigration emerges from a variety of disciplinary perspectives. Sociologists preface the various push and pull factors that move people in and out of agriculture. Demography takes into consideration the scale of contemporary migration for agricultural purposes. Political economy focuses on such things as the citizenship status of migrant farmworkers today – the precarity that illegal political status might entail for migrant workers, in Greece (Lawrence 2007) or in the USA (Holmes 2013). Philosophy (and all of us

presumably) might weigh the ethical considerations. In this vein, ethnographic or anthropological analysis may add an understanding of the existential problems that migrant laborers and farmers face in order to make some kind of living for themselves. Anthropologists may consider the extent of social suffering that groups endure resulting from the cumulative effects of late capitalism on people and land or the ways that agrarian or ethnic identity is threatened in the midst of unprecedented immigration into rural areas (Verinis 2015). While migrants are often perceived as threats to local identities, they also often bring pieces of their homelands with them and engage in agricultural pursuits on their own terms in order to reenact and revive cultural histories in their adopted, globalized homes (Klindienst 2006).

Identifying Immigrants in Agriculture Today

As mentioned above, agriculture has entailed the practices of various groups of people – farmers, cultivators, agrarians, peasants, and so on. Today, agriculture primarily involves the labor of migrant farmworkers. Immigrant participation in agricultural production serves the need in economies of so-called “developed,” “industrialized,” “first world” countries for rather laborious and low-paid handwork, often called “dirty work” (Cole and Booth). Thus while mechanization has limited the need for certain forms of harvest work such as cotton picking or potatoes and has begun to make an impact in other areas such as in the olive, peach, and raisin industries, strawberries, flowers, and other particularly delicate crops will most likely continue to require delicate hand work from migrants across national borders in “undeveloped” or “third world” countries.

Migrants in such dirty jobs are typically male, due to patriarchal cultural structures in both sending and receiving countries, as well as the fact that migration as well as the work migrants endure is generally even more dangerous for women. This is despite some recent trends, as part of a larger feminization of labor on a global scale, in which

migrant men increasingly do traditionally feminine work and women are increasingly employed in areas such as agriculture that have long been more the domain of men. In the agricultural sector, as elsewhere, this feminization of labor often results from the ability for employers to pay women less.

There are official seasonal migrants as part of Gastarbeiter or “guest worker” programs, in Germany and Canada most notably. There are numerous unofficial forms of immigration as well as a multitude of ways that illegal migration patterns serving agricultural needs come about. Chain migrations feed both official as well as unofficial and illegal migration waves. The North African presence in Italy or the Mexican presence in the USA is largely made up of groups of workers who share familial and regional ties, those which they rely on in order to obtain work. Migratory projects in which migrants intend to return home at a certain point are common. Albanian migrants in Greece often regularly return home with olive seedlings in order to create olive farms there that they intend to work in the future. Other economies also result from repetitive movements between host and home countries. Cole and Booth (p. 79) write of Polish men who seek to purchase cars while working in Italian agriculture in order to sell them back home. Thus, migrant identities – as “primitive,” “dirty,” or “dangerous,” illegal, guest, entrepreneur, and so on – are often directly linked to their relationships to agriculture today.

Of course permanent settlement and citizenship status are also goals migrants working in agriculture often have. In the case of immigrants such as Ali, an Algerian in Sicily (Cole and Booth, p. 84), or Lurka D., an Albanian in Greece (Nitsiakos 2003), migrants are often described by ethnographers as assuming or embodying the cultural repertoires of their adopted countries. In so doing, these individuals may also realize the goals of their hosts, as in the case of Lurka D., who becomes “like a son” to a farmer with children who have moved abroad. Here we broach the topic of replacement migration, in which a need for a workforce as well as an emotional need for family or community is satisfied by migrant farmworkers (Van der Geest, Mul, and Vermeulen 2004).

Ethical Concerns

We can investigate ethical dilemmas that emerge at the intersection of agriculture and immigration from a number of different angles as well. There are the ill effects migrant agricultural practices might together have on soil, water, and air quality to consider. Animal cruelty, however conceived, is certainly also gauged by taking into account the particular ways immigration might facilitate one form of animal husbandry or another. Indeed there must also be a variety of ethical quandaries that will result from further and future analyses. Without conceding that there are strict boundaries between the suffering of animals, plants, human beings, etc., the ethical concerns we take most note of here are those revolving around the experiences of human migrant farmworkers.

The bodily *sufrimiento* experienced by Mexican border-crossers (Holmes 2013) and the narrow range of social protections afforded migrant guest workers from South Asia and Mexico in Canada working within Canada's Temporary Foreign Worker Program (Preibisch and Otero 2014) are two prime examples of sites scholars explore so as to conceptualize the ethical dilemmas late capitalist agriculture has created for all of humanity. The tomato harvest in Sicily is similarly "a recognized symbol of immigrant exploitation" (Cole and Booth, p. 3).

Along with the generally precarious nature of illegal farmworker status and the overall social suffering shared across communities with large numbers of migrant farmworkers, there are a slew of other particular ethical issues surrounding immigrant farmwork that stem from industrial-scale, globalized agriculture. Agriculture is one of the most physically brutal forms of work that migrants now tend to do, along with domestic work and prostitution. Fear of losing work or of deportation forces immigrants into all sorts of dangerous situations – working long hours, submitting to squalid housing, hazardous forms of transportation, and so on – which, taken together and in extreme cases, can constitute a form of slavery. All of this threatens the physical and emotional well-being of agricultural workers.

Migrant farmworkers are exposed to toxins used to sterilize soil or repel pests as well as intense heat (in farm fields as well as in greenhouse operations). They tend to suffer from a lack of running and sanitary water as well as heat in largely inhumane accommodations. They specifically suffer from joint and respiratory ailments. Cole and Booth describe this combination of medical problems as characteristic of the typical North African male migrant agricultural worker in Italy.

Migrants have significantly less access to health care, due to legal status, language barriers, as well as other discriminatory structures and behaviors that infringe upon their human rights. Holmes describes the benefits US farmers (and all US citizens for that matter) enjoy in having an illegal labor force that has no choice but to seek health care outside the country – "externalizing the cost of labor force renewal" (2013, p. 13).

The reproduction of poverty is one basic way scholars conceptualize the unethical nature of the relationship between immigrants and agriculture today. Martin, Fix, and Taylor (2006) trace a rather direct line from early American plantations based on slavery to contemporary commercial farms dependent on "willing" migrants. As the transcontinental railroad was built and investments in irrigation systems were made to support urban US consumers (primarily along the east coast), migrant agricultural labor became increasingly necessary to continuing US industrial development. Chinese made up 75% of the workforce in California agriculture in the early 1880s. Japanese and South Asian migrants followed soon thereafter. Mexicans and Filipinos came after WWI (along with Dust Bowl refugees). This is the beginning of what has been referred to as a US immigration treadmill, that which was enshrined in an official guest worker program known as the Bracero Program in 1942. While 51,000 Mexican immigrant farmworkers had unofficially come and gone between 1917 and 1921, 4.5 million Mexicans had done so before the end of the Bracero Program in 1964. Overall one-sixth of the adult men in Mexico were given immigrant status through Bracero.

Like most official as well as unofficial immigration programs, Bracero enabled farmers to

plant broccoli and rely on migrant workers who would be made available. Encouraging Mexicans to offer their cheap labor reinforced overall American economic growth. What Martin, Fix, and Taylor (p. x) call “the new rural poverty” results from expanding labor-intensive fresh fruit and vegetable production and rising Mexico-US migration. After the end of the Bracero Program, in the 1980s, many Mexicans suffering from peso devaluations and economic restructuring still had little choice but to migrate to the USA. The Immigration Reform and Control Act (IRCA) of 1986 legalized 1.2 million farmworkers (90% of whom were Mexican). And there are relatively no penalties for hiring undocumented workers. The ease of obtaining false documents and feigning ignorance also supports the continuation of undocumented work. Unauthorized workers have tripled since the 1980s. At least half of the five million Mexicans entering the USA in the 1990s found employment first in the agricultural sector.

The treadmill continues, despite current political opposition to immigration as well as theories that Mexicans are increasingly unwilling or less in need of such low-wage and precarious work. Rural Mexico has too many people to sustain, in that it produces only 5% of the country's GDP. Some studies (Charlton and Taylor 2013) indicate that there are now fewer lower-skilled workers in rural Mexico due to a sharp decline in fertility and the expansion of rural education. Competition from Mexican farms may also contribute to the recent decline in farm labor supply. Mechanization has threatened a lot of this too. Five thousand local workers operate machines that harvest around 11 million tons of tomatoes in the USA today – five times more tomatoes than during the Bracero era. Yet there are many industries that remain dependent on migrant workers. Farmers, meatpackers, and others who employ migrants in US agricultural industries often insist they could not survive without these workers.

In sum, as Martin, Fix, and Taylor ask with regard to this case, is the USA to blame for “re-creating rural poverty by allowing farmers to hire migrants whose seasonal employment leaves them with below poverty-level earnings?”

Future Engagements of Immigrants in Agriculture

We can be sure that there will be a continuation of such push and pull factors that move citizens of one country to participate in farming endeavors in another, on part-time as well as more permanent bases. That these groups of people will be exploited in one manner or another by global capitalist economic and political structures is also most certainly to continue.

However, the ideal of a free flowing capitalist circuit – between the demand for cheap agricultural labor in wealthier countries and the supply of impoverished people willing to pursue “dirty” agricultural work there – has most recently been compromised by the events of September 11, 2001, in the USA as well as other acts of “terrorism” around the world. While the current global refugee crisis (which entails the forced migration from predominantly Muslim countries and the largest since WWII) would perhaps serve this demand in Europe and North America quite well, reactionary political and legal forces severely complicate a more abstract capitalist scenario.

Along with the fear and exploitation of migrants, there are other more positive relationships developing between hosts and migrant laborers in the agricultural sectors of some first world democracies. There are programs for economic migrants and refugees in the USA that encourage permanent settlement and agricultural entrepreneurship. State, national, and private non-profit programs such as the New Farmer Development, the Agriculture and Land-Based Training Association, and the New Entry Sustainable Farming Project seek to capitalize on the know-how and capabilities of immigrant farmers, satisfying the desires of a diverse array of rural stakeholders there, reestablishing diversified farming practices, a place for agriculture and rurality in the twenty-first century USA, as well as the specific needs and desires of many immigrants engaged in agriculture.

There are also somewhat unprecedented economies emerging as agriculture and immigration continue to intertwine with one another in the

postmodern era. A connection between heritage crops and ethnic identity, in the USA and Europe in particular, also encourages a more sympathetic approach to immigrant involvement in agriculture. The *Nuestros Raíces* or “Our Roots” community garden in South Holyoke, Massachusetts, serves as evidence that multiculturalism, small-scale agriculture, and culinary diversity are alive in some places (Klindienst).

Conclusion

In considering agriculture and immigration in tandem with one another, we must consider the positions of local farmers, migrant farmworkers, as well as settled immigrant farmers in particular. We must strive to consider all the individuals and phenomena that together make up the ecological histories, political economies, and symbolic structures in which immigration for agricultural purposes takes place. Yet in ethical as well as many other terms, the most noteworthy protagonist in these stories about the current era of late capitalist agriculture is the contemporary migrant farmworker. As Cance wrote in 1925, “any attempt to secure capable and efficient immigrant farm laborers will be vain as long as opportunity is given to purchase or rent land” (p. 107). In this way, flexible and cheap immigrant farm labor continues to be supported by social, economic, political, legal, and symbolic/cultural structures which disallow most migrants on foreign soil to move beyond the status of immigrant agricultural laborer or farmworker and secure stable, fair-paid employment or resources such as land.

Along with their exploitation, there is no denying the broad spectrum of socioeconomic benefits migrants bring to rural communities, despite or perhaps because of the difficulties they face. Mexicans in the rural US communities they came to spend time in at the turn of the twentieth century certainly did contribute greatly to regional economies. And farmers of Hispanic heritage now make up a significant proportion of American agriculturalists, in California most notably. Their roots are predominantly immigrant roots that have run

around all sorts of obstacles, for the benefit of all Americans, now including themselves.

Of course state, national, and regional/global political economies will conceive of their own relations between hosts and immigrants in the future. There are new postindustrial mobility patterns that entail agricultural pursuits to varying degrees. Internal migrations in the forms of counter- as well as counter-counter-urbanizations in Greece, for example, push and pull migrants in and out of that country (Gkartzios 2013). And there are significant new refugee migrations to consider around the world. These mobilities may emerge from financial crises, new border restrictions, ongoing war, or other causes. Many of them are sustained, in large part, by agricultural economies.

In any case, the trajectory is currently along the same ethically problematic lines we have reviewed here. As Cance concluded in 1925 (p. 111), “The third generation should develop a splendid type of farmer and citizen. Suppose we again induce a flow of new immigration, with lower ideals of education, home life, and standards of comfort?” While Cance was speaking about the generations of immigrants coming to farm in the USA in the early twentieth century and was more concerned with settling farmers so that their grandsons become proper “civilized” citizens, he is, as we are here and now, writing against the scenario in which US agriculture relies on immigrant workers denied the opportunity to prosper.

Introduction

Making meat through tissue engineering is an idea under investigation. It has been attracting attention from many sides. For example, both animal activists and private investors, after initial hesitation, have tended to embrace it, because of its promise for animals and its innovative and disruptive market potential, respectively. Artists and designers have been triggered to play with the idea. Journalists have for years been wondering when it will appear on our plates.

In this contribution, I am interested in cultured meat against the moral background of the now widely shared idea that global levels of meat consumption are highly problematic for both animals and the planet. But I will not draw definite moral conclusions about the desirability of cultured meat as a product. In the context of the search for meat alternatives, cultured meat is not the only hopeful candidate. My question in this entry is what its place has been so far, and might be in the future, within this search. For that purpose, I will first briefly sketch historical developments, in four steps, illustrating how cultured meat and its context mutually change and shape each other. After that, I will emphasize how processes of change concerning meat are characterized by multiple tensions, conflicts, and ambiguities. I will go into some of them, arguing that such understanding is needed in order to get a better understanding of moral change.

A Brief History in Four Steps

Emergence of an Idea

The idea of cultured meat is to grow animal tissue on the basis of animal cells through tissue culture techniques, with no real animal involved. As an idea, it is not particularly new. Winston Churchill's prediction that "we shall escape the absurdity of growing a whole chicken in order to eat the breast or wing, by growing these parts separately under a suitable medium," in his essay *Fifty Years Hence* (1932), is widely cited as the first time the idea appeared in print. At the time, this suggestion did not seem at all urgent; it was a solution without a problem. Worries about meat only began to take societal form more than 30 years later, when meat consumption had begun to increase greatly in the Western world and Ruth Harrison's *Animal Machines* (1964) protested against the instrumental use of animals in factory farming. But in the 1960s, those problems were not a reason to remember Churchill's idea. There were other options. In *Diet for a Small Planet* (1971), Frances Moore Lappé argued that the perfect alternative for meat had long been available and consisted in a combination of pulses an

grain. She included many recipes to facilitate the change for meat eaters. Although the book became a bestseller and was translated in many languages, pulse consumption, already in decline, continued to go down, while meat consumption continued to rise, and still rises on a global scale; as the world becomes both richer and more populous, pulses are being left behind as "meat for the poor."

Plant-based burgers and other meat alternatives appeared on the market but did not really gain much ground either. Nothing really seemed to work. It was in this climate, around the turn of the century, that the idea of cultured meat was rediscovered by a variety of people and groups. The Dutch business man Willem van Eelen, who independent of Churchill had thought of the idea some decades earlier, acquired a patent in 1998, even though the method could not be put in practice. NASA temporarily funded research by Morris Benjaminson on fish tissue culturing with an eye on protein production during space flights. Bioartist Oron Catts cultivated frog tissue and served it as "victimless meat" during a museum performance, in the presence of the living donor-frog in 2003 (Catts and Zurr 2007). Jason Matheny was an American student who had become appalled by industrial chicken farming and, inspired by Benjaminson's work, founded the lobby organization *New Harvest* in 2004 (Pincock 2007). The combined efforts of Matheny and Van Eelen led to a 4-year research program (2005–2009) in the Netherlands. Cultured meat became a promise; it could offer something that none of the other alternatives could; a product that would solve the major problems of meat and yet would really be meat.

2008: Real Meat!?

Let me pause for a moment in 2008, when during the first scientific conference on in vitro meat, in Norway, it was concluded, that consumer acceptance was a very uncertain aspect (Haagsman et al. 2009). Yet also in 2008, and after much internal discussion, the animal organization PETA (People for the Ethical Treatment of Animals) decided to consider cultured meat as a road to serious meat reduction and offered a one million dollar prize for

bringing in vitro chicken meat to the market by 2012. One condition was that it should not be distinguishable from normal chicken. The contest testifies both to the feeling that cultured meat might finally be a viable meat alternative, and to the (however reluctant) pragmatic turn of prominent vegan animal campaigners, who needed to accept the use of at least some animal material in order to be able to support cultured meat.

In the same year, Hopkins and Dacey (2008) published an ethical review of the pros and cons of in vitro meat, based on the same idea, that this might finally be a convincing alternative, as the subtitle of their paper indicates: *Could technology save animals and satisfy meat eaters?* The arguments for cultured meat, they said, are very clear and straightforward and “in essence the hopeful outlook of a technological fix”; IVM could eliminate much animal suffering and environmental damage, and it might produce healthier food. They also considered many objections and hesitations, such as worries about unnaturalness and about yuck responses and the idea that technological solutions amount to “moral cowardice – choosing a quick fix over genuine moral work.” In their analysis, none of the objections carries enough weight to counter the potential gains. The alleged “unnaturalness” of cultured meat may be precisely what we are looking for, since at least some of the “natural” ways of producing meat are so problematic. Yuck responses are interesting and important but can hardly count as final judgments, and the argument from moral cowardice at best “suggests we should not be so naïve as to think technology can simply solve all our problems; it should not however lead us to think that technology cannot be a powerful moral tool” (p. 591). After weighing pros and cons, they conclude that cultured meat is not just interesting, but “something we may be morally required to support.” They also note, more generally, that morality need not simply respond to new technologies as they arrive; it can also be guiding; it may “champion and assist” in the development of technologies as steps towards a better world.

Van der Weele and Driessen (2013; see also Driessen and Korthals 2012) responded to this analysis by agreeing with it as an argument for

research, not for cultured meat as a (not yet existing) product. At the same time, we argued that this early situation was a chance to apply moral imagination to cultured meat, taking seriously doubts and worries in order to develop desirable future scenarios. We distinguished two different existing profiles for cultured meat: one that aimed at more sustainable meat and one that aimed at the elimination of animal exploitation. Our experience in workshops and discussions suggested the attraction of a third profile (which we called “the pig in the yard”) that emerged from the widespread ambivalences that were triggered by the idea of cultured meat. This profile came with a scenario that focused not on a product but on a production process; cultured meat was to be made in small local factories with cells from animals that were kept in yards and small farms; it consisted in a combination of new technologies, old traditions, and new sensibilities. Tinkering on the basis of ambivalence, we argued, might lead to the development of new options and new moral identities in dealing with animals and meat. I will pick up this line of thought below. Let me first continue the brief history of the interaction between cultured meat and its context – the search for meat alternatives – through a closer look at 2011.

2011: Patience

Money for in vitro *meat* research was extremely hard to find, and in 2011, during a workshop in Gothenburg, the in vitro meat community estimated that on a worldwide scale, only a handful of people were working on the development of cultured meat, while the scientific and technological challenges were serious and manifold, ranging from the need to understand stem cells and grow them in a vegetarian medium to the problems of scaling up. The participants also thought that a change of name might help; cultured meat might be a more attractive name than in vitro meat.

But 2011 was also the year when tides began to turn, mainly through private money. Mark Post acquired private money for the development of a “proof of principle” hamburger (which he presented in 2013), Andras and Gabor Forgacs

acquired money for a start-up company, *Modern Meadow*, that focused not only on cultured meat through 3D-printing but also and increasingly on cultured leather (so that its motto became “Leather re-imagined”). On the artistic front, designer Koert van Mensvoort made his students at Eindhoven University design cultured meat products, which resulted some years later in *The In Vitro Meat Cookbook* (Van Mensvoort and Grievink 2014).

Silicon Valley Discovers Food

In recent years, Silicon Valley has been discovering food in general and alternatives for animal products in particular (Fehrenbacher 2013). An increasing number of start-up companies, backed up by an increasing amount of venture money, develop an increasing number of alternatives for animal products, with the help of a variety of technologies. Plant-based meat alternatives are very prominent and aim to mimic meat ever more perfectly, on the basis of the widespread conviction that “humans are hard wired to go crazy for meat” (Jacobsen 2016). Their initiators are characteristically vegans who came to the conclusion that making products that are indistinguishable from real meat will provide a quicker change to an animal friendly and more sustainable world than working through NGOs and governments. Patrick Brown, for example, a Stanford professor who at first counted on “a little education” to convince the world of the need for change, after organizing a national workshop which “caused not a ripple” concluded that the free market was the only way and set up the company *Impossible Foods*. He is quoted as saying that “it’s easier to change people’s behavior than to change their minds.” (Jacobsen 2016; see also Purdy 2016).

These developments have greatly been changing the context for the development of cultured meat. It became part of a wider field of research and development, which now aims to replace many animal products, not just meat but also milk, eggs, leather, perfume, etc., by products made on the basis of plants, or animal cells, and/or with the help of a variety of biotechnological and synthetic tools. Lobby organization *New*

Harvest made a shift from promoting just cultured meat to the promotion of this wider field, calling it “cellular agriculture,” with the ultimate aim of creating a “post-animal bioeconomy”. The *Good Food Institute*, working with scientists and entrepreneurs, also includes both plant-based alternatives and “clean meat” – which it sees as a more marketable name than cultured meat. So plant- and animal-based alternatives are now being developed in parallel. While new and increasingly meat-like plant-based alternatives regularly appear on the market, the competition for the first cultured meat is also speeding up; early in 2017, *Memphis Meats* presented its work on cultured chicken and duck, aiming for a marketable product by 2021; a few months later, *Hampton Creek*, known for its plant-based alternatives, announced that they were also working on cultured meat and hoped to get it to the market within 2 years (Purdy 2017).

Understanding Tensions

The brief history above is meant to illustrate the interaction between cultured meat and the context in which it develops. When it was first proposed, meat was hardly seen as a problem, so there was no need for alternatives, let alone weird ones. When problems of meat began to become apparent on a wider scale, a perfect solution was also seen to be available, in the form of pulses. But after several decades, meat consumption increased ever harder, while pulse consumption continued to decrease, and plant-based alternatives remained marginal. Suddenly, cultured meat, with its promise of being really meat, appeared to be perhaps the only viable alternative; the solution had found its problem. That cultured meat implies an acceptance of the attractions of meat may help explain that it makes people talk not only about cultured meat itself but also about the attractions and disadvantages, in short the ambivalences, of “normal” meat. At the same time, cultured meat helped establish the conviction that meat alternatives, while being radically different from meat on the one hand, should resemble meat as closely as possible on the other

hand, a conclusion that has also been drawn on the basis of consumer research (Hoek 2010, Hoek et al. 2011; see also Zaraska 2016). At present, plant-based burgers too ever more perfectly resemble meat, while their sustainability profile is more positive. This implies a new change of context for the profiling of cultured meat.

This process of interactive change centrally involves moral change, but it complicates a clear-cut moral evaluation. The process involves various kinds of changes and tensions: ambivalent valuations of old as well as new options (e.g., meat is both loved and hated) and widespread uncertainties and ambiguities concerning the meaning and significance of new options (is cultured meat just simply meat?). Understanding processes of moral change requires attention for these tensions. Let me briefly go into four of them, all interwoven, as they emerged in the literature as well as my own research.

Meat: Both Good and Bad

Around the turn of the century, Holm and Møhl (2000) found in interviews among Danish meat eaters that many of them had much the same problems with meat as vegetarians. People were especially negative about factory farming. But they had different ways of dealing with their problems than vegetarians; they bought, for example, minced meat to avoid associations with animals. This is a sign of ambivalence about meat, for which various ways of coping have been described, caught in various theoretical terms and frameworks. Bastian et al. (2012) found how in order to reduce cognitive dissonance, people ascribe lower mental capacities to animals they eat (pigs, cows) than to animals they don't eat such as cats and dogs. Graça et al. (2014) found that in order to continue their meat habits, people morally "disengage" from the issue. Onwezen and van der Weele (2016) found evidence for "strategic ignorance." They observe how a lack of behavior change has been associated with indifference in consumer studies, because values were supposed to be well-ordered and linked to behavior. But it is increasingly clear that the valuation of food, and especially meat, is subject to much tension, and that ambivalent lack of action is not the same as

indifference (Van der Weele 2013; Onwezen and Van der Weele 2016).

In discussions and focus groups on cultured meat, we found that cultured meat quickly and invariably triggered ambivalences concerning meat. For example, when someone remarked that cultured meat is very unnatural, someone else was bound to question the naturalness of factory farming in response (Van der Weele and Driessen 2013). This takes us to the next ambivalence:

Technology: For or Against Nature?

Hopkins and Dacey said that the unnaturalness of cultured meat speaks for it, since our "natural" ways of producing meat are so problematic. In a very different vein, Simon Fairlie (2010), arguing for organic food, slow food, and (modest amounts of) "real meat," saw cultured meat as a continuation of factory-produced protein, which will converge with genetic engineering and lead to estrangement from nature. In response, Welin and I (Welin and Van der Weele 2012) replied that our relationships with animals and nature may in fact improve through cultured meat, if it makes factory farming disappear, thus putting an end to much destruction of nature caused by the need to feed all those animals. Clemens Driessen and I (Van der Weele and Driessen 2013) encountered the idea of improved relations with animals through the "pig in the yard" scenario, which immediately turned the ambivalent participants into enthusiasts for cultured meat. A local technology that would allow good relations with animals and close contact with the origins of food seemed almost too good to be true to them. In later workshops, participants found that idea indeed too good to be true; they found it much more realistic to think that cultured meat will be made by large companies, which takes us to the next ambivalence.

Disruptive Innovation: From High Tech to Pulses?

Cultured meat is clearly meant to be a disruptive innovation; it is intended to improve the efficiency of making meat while getting rid of the moral price by putting an end to factory farming.

At the same time, technological innovation is expected to make a farm resemble a factory ever stronger (Carr 2016) and cultured meat certainly fits in that expectation as well. While small-scale factories met with warm sympathy in our workshops, food production in the hand of large and powerful companies was a reason for distrust. Now that Silicon Valley tech-giants, which disrupt old technologies, job markets, as well as communities, have become the richest and most powerful companies in the world, such distrust is certainly growing. So the new collaboration between animal activists and Silicon Valley venture capitalists is a reason for considerable moral ambivalence. Factory farming may deserve disruption, but why does it need to be high-tech, capital-intensive, and inequality-promoting? Why do economic models leave so little room for social and “common” innovation? (Swann 2014) and why cannot we disrupt factory farming through the good old pulses, which are more sustainable than even the most efficient high tech products will ever be, as the latter will always involve the losses that come with industrial processing? Should not the reputation of pulses shift from “food for the poor” to “food for the rich”? This takes us to a next ambivalence.

Meat Alternatives: How Meatlike Should They Be?

Cultured meat has helped to shape the present search for meat alternatives that perfectly resemble meat, based on the assumption that humans crave meat, have a built-in preference for meat, etc. This assumption does not take into account other forces, for example, that for most of history meat consumption has been much lower, that status is a factor in meat consumption, that present levels of meat consumption represent big economic interests and that human behavior is also subject to the force of changeable social norms.

As people are defined as meat craving beings, it is often thought that cultured meat and even plant-based burgers should be marketed as “simply meat.” Yet these products make a difference precisely because they are not simply meat. The result is that companies have to “negotiate a careful balance” between positioning their products as

meatlike in some respects and very different from meat in others, as Alexandra Sexton (2016) puts it. In our focus groups (Van der Weele and Driessen 2014; Van der Weele 2017), it was the combination of similarity and dissimilarity between cultured meat and meat that made people respond sympathetically.

The difference between young and old people in these groups was interesting. Beforehand, we expected that younger and urban people would be more interested in cultured meat than older and rural people, but we found no evidence for that. Instead, we found a different of approach; the young tended to wonder whether they would eat it (answering yes if it perfectly resembled meat as they knew it), while the old tended to respond as observers of societal process. For example, based on the awareness that meat has become problematic (“We eat far too much meat nowadays”), they tried to think of market strategies to turn cultured meat into a success (“McDonalds should do this”). Knowing from their own experience that food habits change (“margarine was also very strange at first”) and that people can get used to many new things, it seemed far less mandatory that meat alternatives are indistinguishable from meat.

The assumption that alternatives need to resemble meat has an uncertain future. For example, when meatlike products are no longer associated with raising and slaughtering animals, will they continue to be compared to meat? May resemblance to meat become a weakness for people who don’t want to be reminded of their old meat-eating habits? The contingency of the ties to meat often surfaced in our focus groups: “If we are to eat less meat, why not simply choose beans and lentils?”

Conclusion

Cultured meat began as a strange and seemingly useless idea, then came to look like a perfect alternative for meat and is now on the verge of becoming one meat alternative among many. The field of meat and its alternatives is characterized by big challenges and developments and also by much ambiguity and ambivalence and

uncertainty. Zooming in on some of the ambivalence, I have been arguing that they are important signs of moral activity and change. They represent issues about which cultures, institutions, and people are divided not only among each other but importantly also within themselves. Devising directions and solutions that go beyond the societal polarities and stalemates requires insight in those tensions, as well as creativity and imagination for dealing with them. So far, cultured meat has helped; as a mere idea, it has been and continues to be a tool for replacing polarities concerning meat with ambivalences and with imagination and open-mindedness. Whether it will also be successful as a product is still open.

Introduction

This entry discusses the food practices of Northern Indigenous peoples of Canada and the United

States, specifically, First Nations, Inuit, and Métis in Northern Canada, and Alaskan Natives in the United States. It includes Indigenous peoples living in the geographic regions of the North American Arctic and Subarctic. Indigenous peoples of Canada and the United States have historically relied on a diet comprised primarily of traditional foods. The traditional food system refers to “all food within a particular culture available from local natural resources and culturally accepted. It also includes the sociocultural meanings, acquisition/processing techniques, use, composition, and nutritional consequences for the people using the food” (Kuhnlein and Receveur 1996, p. 418). Traditional foods vary by season, geography, and cultural group (Earle 2013) and are also termed country foods, wild foods, land- and water-based foods, and forest and freshwater foods by various Indigenous peoples and scholars. Traditional foods have documented nutritional, cultural, and spiritual benefits for Indigenous peoples. With the migration of Indigenous peoples further from their home communities, and often into urban environments, traditional foods can include non-local foods transported to urban centers from Indigenous communities.

Since first contact with European settlers, Indigenous food systems have comprised both traditional foods and market-based foods (also termed processed foods, industrial foods, imported foods, store-bought foods, purchased foods, and commercial foods), which were introduced by settlers. The introduction of market-based foods has resulted in a diet based on foods from both food systems. The contribution of market-based or traditional foods varies depending on the time of year, the household, individual, and community (Ford 2009). In many Northern communities, market-based foods are available for purchase from a few small stores, including those owned and managed by The North West Company, which began as a company specializing in fur trading (The Hudson’s Bay Company), but now sells grocery items in many Northern communities, and the Canadian Arctic Co-op, a member-based grocer in the Canadian Arctic. Many remote Northern

communities have only one grocery store that carries fresh, perishable foods. Some communities with year-round road access do not have a grocery store, forcing them to travel long distances to neighboring communities to purchase food and other goods. Perishable and non-perishable goods are also purchased by individuals and shipped via airmail. In Canada, the federal government implements the Nutrition North Canada program (which in 2011 replaced the longstanding Food Mail Program – a program that operated as a transportation subsidy through Canada Post), to subsidize the cost of nutritious, perishable foods to communities in Northern Canada that lacked continual road access throughout the year. The Nutrition North Canada program operates with a direct subsidy to registered retailers with the expectation that the subsidy is passed on to consumers. The program has been critiqued for not being effective in lowering market-based food costs for Indigenous households and that not all remote communities in Canada are eligible for the full subsidy (Burnett et al. 2015). Nonperishable market-based foods are also shipped into some communities on sealifts (often once a year), via mail, or purchased on visits to larger communities.

Dietary and Lifestyle Transitions and Health

The historical diet of Indigenous peoples varied by cultural group, season, and location, but generally the diet was high in animal protein, low in fat (other than marine sources of fat), and nutrient-rich. The lifestyle associated with traditional food procurement required high energy usage due to the physical demands of hunting, fishing, trapping, gathering, and food preparation (Earle 2013).

In the North American Arctic and Subarctic, the increase in permanent settlement from the 1940s onward is cited as an influence on the dietary shift toward dependence on market-based foods and away from traditional foods (Kuhnlein et al. 2006). With each generation, there is a decrease in consumption of nutrient-dense

traditional foods and an increase in market-based foods. Often the more accessible, available, and affordable market-based foods are nutrient-poor. The market-based foods in the North are usually of inferior nutritional quality, and the increase reliance on market-based foods is associated with increased consumption of foods high in refined carbohydrates, including sugars, fats, and sodium (Kuhnlein et al. 2006; Egeland et al. 2011). This dietary transition is associated with a lifestyle transition, where traditional activities of food procurement (hunting, fishing, gathering) are declining and lifestyles are becoming more sedentary (Earle 2013). Evidence across Canada and the United States indicates that this diet and lifestyle has implications for Indigenous peoples' health, as health outcomes for Indigenous peoples are consistently poorer than the general North American population (Kuhnlein et al. 2006), and Indigenous peoples have higher rates of diabetes, heart conditions, and obesity than the general population. A diet high in traditional food consumption has been shown to reduce risks of disease and conditions that are prevalent in Indigenous populations, including diabetes, obesity, cardiovascular disease, and mental health (Earle 2013). Consumption of traditional food improves diet quality and nutrient adequacy due to high levels of antioxidants, omega-3 fatty acids, monounsaturated fatty acids, protein, and other micronutrients.

Beyond physical health, the consumption of traditional foods is important for Indigenous spiritual, mental, and community health. Among Northern Indigenous peoples, health is considered a holistic concept. A common framework for describing the health of Northern Indigenous peoples (with variations within each group and community) is a medicine wheel that includes four quadrants – physical, spiritual, intellectual, and emotional health (Svenson and Lafontaine 2003). Traditional food is important for the maintenance of Indigenous individual health and culture (Power 2008), and eating traditional foods is often linked to individual warmth (Borré 1994), strength, and health (Searles 2002).

Threats to Northern Food Systems

There are multiple documented challenges to both traditional and market-based food systems in the North. A leading environmental threat to the traditional food system is the contamination of food sources by a variety of environmental contaminants, including persistent organic pollutants and heavy metals. Research in the Canadian North has shown that Indigenous exposure to heavy metals is higher than most populations living in the South, due to the consumption of traditional foods. Risk assessment and communication around the threats of environmental contaminants in traditional foods has sometimes led to negative impacts, including anxiety and stress and decreased traditional food procurement and consumption (Donaldson et al. 2010). Both the market-based and traditional food systems in the North are particularly vulnerable to the impacts of climate change (Furgal and Sequin 2006; Ford 2009). Climate-related conditions affect access to hunting grounds (e.g., sea-ice conditions and weather events) and the migratory path, timing, abundance, and health of hunted animals. Changes to these climatic conditions are already being observed by hunters (Ford 2009; Gerlach and Loring 2013). Climate conditions also affect the availability of market-based foods because of the reliance on ice roads, sea shipments, and flights for transportation of market-based foods (Ford 2009; Gerlach and Loring 2013).

There are a number of socioeconomic and knowledge barriers to traditional food provisioning among Northern Indigenous peoples. Challenges include the cost of necessary equipment and supplies (such as fuel and ammunition) for hunting and fishing, lack of access to traditional lands for hunting and fishing, regulatory frameworks that limit harvesting, a shift in the knowledge base and interests of young people, and a lack of time because of full-time employment (Lambden et al. 2006; Mead et al. 2010; Gerlach and Loring 2013). There are also socioeconomic and knowledge barriers to market-based food consumption. These include the costs of market-based foods, the limited selection of products in small rural stores, the quality and variety that are

tied to the global food system, and the fact that market-based foods do not fulfill the cultural roles that traditional foods do (Gerlach and Loring 2013; Mead et al. 2010).

Indigenous Foods and Culture

For Indigenous peoples, food is more than sustenance; traditional diets have benefits to Indigenous community health in complex and holistic ways (Earle 2013). Food, culture, human health, and ecosystem health are interrelated (Loring and Gerlach 2015). Food is important to Indigenous cultural identity and provides a spiritual and physical connection to the land (First Nations Information Governance Centre 2012). Food has important cultural significance from harvest to consumption. Harvesting traditional foods is one of the main links that Indigenous peoples have to the land and is a main way to transfer intergenerational skills, support cultural values, and maintain spirituality (Power 2008). Cultural values around hunting include respecting and honoring the spirit of the animal, using every part of the animal (Mead et al. 2010), sharing food (Searles 2002; Mead et al. 2010), and the connection between meat preparation and consumption (Borré 1994). Concerns have been raised about the decrease in transfer of traditional food knowledge to young people and the implications of this on the traditional food system (Mead et al. 2010).

Food Practices and Types of Traditional Foods

The practice of food sharing is central to most Northern Indigenous peoples. For example, the Inuit in the Canadian Arctic have a sharing culture that is characterized by general reciprocity and a continual redistribution of individual wealth for the benefit of the community (Searles 2002). Food and the tools and commodities that are of use for food procurement (such as hunting and fishing tools) are more or less communal property of a household or a number of households. Within this system, individuals who contribute more to the communal supply generally have more power and authority, and the successful hunters often become

leaders within their extended families and communities (Searles 2002). In order to show respect to elders, they are served the delicacies such as the liver, kidney, and heart (Food Safety Network 2009).

Northern Indigenous peoples have developed a variety of food preparation and storage techniques that vary based on the local ecosystem and community preferences, with very little wasting of food resources (Food Safety Network 2009). There is some concern expressed by governments over food safety with traditional preparation, storage, and cooking techniques, particularly as it relates to raw food consumption, fermentation, and organ meat consumption. However, Northern Indigenous communities do show traditional knowledge of food safety. Most of the limited documentation on food preparation among Northern Indigenous peoples comes from Inuit and Native Alaskan communities. One method of meat preservation among Inuit is Igunaq, meat (including seal, walrus, and caribou) is aged or fermented by placing both meat and fat tissues into a hide bag that is sewn closed and cached. The specific recipe for Igunaq, including the type of caching and the length of time it is cached, varies both within and between communities (Food Safety Network 2009). Muktuk, or fermented whale blubber attached to the skin, is a delicacy among Inuit and is often consumed raw (Food Safety Network 2009). Other preservation techniques among Indigenous populations include drying, which can be done using air or sun, salting, brining, fermenting, home canning, and pickling. Food storage methods include aboveground and belowground caching and freezing (Food Safety Network 2009). Common cooking techniques include roasting over an open fire, smoking, boiling, baking, and frying (Food Safety Network 2009).

Food Security

The social and ecological legacies of colonialism and federal land claim settlements have made significant negative impacts on food insecurity for Indigenous peoples. Studies have shown a

high prevalence and severity of household food insecurity in many Northern communities, and food insecurity has been increasing in the North American Arctic and Subarctic (Expert Panel on the State of Knowledge on Food Security in Northern Canada 2014; Loring and Gerlach 2015). It is a serious and pervasive public health issue for Indigenous peoples living in the North American North. To acknowledge the unique food security considerations (i.e., the harvesting, sharing, and consumption of traditional food) and the vital importance of traditional food for the health and survival of Indigenous peoples, “cultural food security” has been proposed as another level beyond individual, household, and community food security (Power 2008). The conceptualization and measurement of food security need to consider both traditional and market-based food systems (Power 2008).

Some of the key factors contributing to these high levels of food insecurity include an over-connectedness to the global system, impacts of contaminants and pathogens on the quality of subsistence foods, and management and governance constraints (e.g., restrictive land tenure regimes) (Loring and Gerlach 2015). Within these broader categories, numerous key factors affecting food security include high rates of poverty and unemployment; food sharing networks; environmental contamination of the traditional food supply and global climate change; access to the land; loss of traditional knowledge; the cost, availability, and quality of commercial market foods in remote communities; the processing, marketing, and sale of traditional food; and the prevalence of other pressing social issues (Power 2008). Additional factors include living in urban cities and the presence or absence of community-based programs.

There are existing community-based responses to food insecurity in Indigenous communities, such as food banks, food cooperatives, good food boxes, community kitchens, community gardens and greenhouses, community freezers, and school food programs. These initiatives vary by community and are often organized by local volunteer community food activists or by local health authorities and centers. There is a general

consensus that community-based and community-led solutions to food insecurity are necessary and that access to local food improves food security (Kuhnlein et al. 2006; Loring and Gerlach 2015).

Food sovereignty is a concept that arose from the inadequacy of food insecurity analysis to address power relationships in the food system. Further, Indigenous food sovereignty is based on the responsibility that Indigenous peoples and communities have to “uphold our distinct cultures and relationships to the land and food systems. Indigenous food sovereignty describes, rather than defines, present-day strategies that enable and support the ability of communities to sustain traditional hunting, fishing, gathering, farming, and distribution practices” (Morrison 2011).

Conclusion

This entry has focused on Indigenous peoples and food in the North American North (the Arctic and Subarctic in Canada and the United States) including the three Indigenous groups in Canada (First Nations, Métis, and Inuit) and one Indigenous group in the United States (Alaska Natives). There is an intersection and evolving nature of the two coexisting food systems (traditional foods and market-based foods) for Indigenous peoples and the related dietary transitions that have been occurring. Food practices, including food acquisition (hunting, gathering, and fishing), preparation, storage, cooking, and consumption (including communal eating and the role of food sharing and exchange) are important for overall Indigenous well-being as are the social, cultural, spiritual, economic, and health aspects of traditional foods. Indigenous foods have challenges with respect to the access to land, food security, Indigenous food sovereignty, and climate change.

Introduction

Over the past 50 years, animal agriculture in the United States (USA) has transformed from an extensive model characterized by many small family farms to an intensive, industrialized model. This industrial model – sometimes called “Industrial Farm Animal Production” (IFAP) or more colloquially “factory farming” – is characterized by frequent corporate ownership, economic consolidation, and vertical integration; the extreme confinement of large numbers of animals; the use of “technological sanders” such as growth-promoting antibiotics; the use and long-distance transport of remotely grown concentrated feed-stuffs, instead of forage or pasture-based feeding;

Disclaimer: The opinions expressed are the authors' own. They do not reflect any position or policy of the National Institutes of Health, U.S. Public Health Service, or Department of Health and Human Services

and tight control over the breeding, feeding, and living conditions of animals so as to achieve the greatest production at the lowest cost and in the shortest amount of time (Singer 2002; Singer and Mason 2006; Foer 2009; Pew 2008). This model has successfully produced a large supply of cheap meat and dairy but at significant costs to animal welfare, the environment, the risk of zoonotic disease, the economic and social health of rural communities, diet-related disease, and overall food abundance.

Over the past 40 years, numerous ethical critiques of IFAP have been published, which discuss the various costs outlined above, though often with a predominant focus on animal welfare (e.g., Regan 2001, 1983/2004; Pluhar 1995; DeGrazia 1996; Singer 1980, 2002; Foer 2009). With very few exceptions, these critiques have concluded that IFAP is morally indefensible. This entry will briefly review the costs of IFAP, the ethical critiques that have been and could be levied against it, and also a few attempted defenses.

The Costs of IFAP

IFAP is associated with numerous and significant costs to animals, humans, and the environment. Here these costs will be briefly reviewed. Because space prohibits a detailed exploration, the reader is encouraged to review the cited resources. First, IFAP exists to provide large supplies of cheap animal products to the consumer public, and this is often touted as an important benefit by the industry itself. However, populations in the developed world are currently struggling with high rates of obesity and chronic disease, and evidence suggests that this is in part due to diets containing large amounts of animal products. Animal products are our main source of saturated fat and our sole source of dietary cholesterol – important risk factors for many of our chronic diseases (Akhtar et al. 2009; Walker et al. 2005). Emerging evidence suggests that plant-based diets offer benefits as compared to omnivorous diets as concerns lower body mass index and all-cause mortality and a lesser incidence of type-II diabetes, hypertension, and certain types of cancer (ADA 2009;

Craig 2009). Properly planned plant-based diets can meet nutritional requirements for all stages of life (ADA 2009), and furthermore such diets are comparable in cost to omnivorous diets (Hyder et al. 2009). Therefore it would be better for the public's health for most persons to transition to diets containing little or no animal products.

Second, many persons in the world already suffer from malnutrition, food insecurity, or even starvation, and these problems will likely only worsen as the global population grows. While these are multifactorial problems, increasing the available food supply can only help to remedy them, and IFAP represents an extremely inefficient way to produce food. The (sometimes overwhelming) majority of the corn, wheat, and soy crop are used to produce feed for animals in concentrated animal feeding operations (CAFOs), and these animals convert only a fraction of the protein they consume into edible meat. For example, the US livestock population consumes more than seven times as much grain as is consumed directly by the entire American population, and the amount of grains fed to US livestock is sufficient to feed about 840 million people who follow a plant-based diet (Pimentel and Pimentel 2003).

Third, IFAP contributes significantly to climate change and environmental pollution. Animal agriculture contributes anywhere from 18% to 51% of global anthropogenic greenhouse gas (GHG) emissions (UN FAO 2006; Goodland and Anhang 2009). It is also the leading cause of ammonia pollution in the United States, at about 75%, which can affect community quality of life on a regional scale. Locally, particulate airborne emissions from IFAP facilities significantly affect rural community health (Pew 2008).

Animal agriculture consumes 70% of the world's groundwater resources (UN FAO 2006); IFAP uses 5-fold more water than extensive animal agriculture and 100-fold more water than plant-based agriculture (Pew 2008). This is exacerbating dangerous water shortages and depletions of the water table already present in some parts of the United States and the world (Pew 2008). Agriculture is the leading cause of waterborne pollution, and much of this is due to runoff of manure from IFAP facilities into waterways.

IFAP produces 500 million tons of manure, more than three times that of the entire human population (Pew 2008). This leads to contamination of major waterways, leeching of nutrients from the soil, and dangerously low levels of oxygen in the water (hypoxia) that can result in major coastal dead zones (Pew 2008). Agriculture uses a large amount of fossil fuels, with between 4 and 39 kcal (average 25) of fossil-energy input required for 1 kcal of meat output. By comparison, 1 kcal of plant protein presently uses 2.2 kcal of fossil-energy input (Pimentel and Pimentel 2003).

IFAP exerts a number of social, economic, and health-related costs on rural communities in which concentrated animal feeding operations (CAFOs) are located. Working conditions in CAFOs and slaughterhouses are documented to be very poor, with hard, often brutal work, high injury rates, and human rights abuses (Singer and Mason 2006; Human Rights Watch 2004). Farm workers in IFAP systems and associated communities are more likely to contract a variety of zoonotic diseases (notably including influenza). Upwards of 30% of CAFO workers have chronic respiratory disease (Pew 2008). These health effects extend to rural communities more broadly, which are at increased risk of respiratory diseases such as asthma, zoonotic diseases, and possibly neurologic disease (Pew 2008). CAFOs often make associated communities aesthetically unpleasant and difficult to live in (Singer and Mason 2006; Pew 2008; Foer 2009). Corporate consolidation has resulted in a decrease in economic investment in rural communities. Large farms making more than \$900,000 annually invest less than 20% of their revenue locally, in comparison to >90% for small farms making less than \$100,000 annually. IFAP-associated communities are associated with greater crime, poverty, and depression and a lesser sense of control and self-determination by residents (Pew 2008).

IFAP imposes massive harm upon animals. Approximately 10 billion animals are raised and killed in the United States per year to provide food. This includes about 9 billion poultry (chickens and turkeys), 100 million pigs, and about 40 million cattle (Humane Society of the United States 2012). Whether death per se harms

sentient (but non-self-conscious) animals has been a point of debate among philosophers, but a good case can be made that it does under normal circumstances (Harman 2011). If this is true, then based solely on the number of animals killed, IFAP inflicts massive harm upon animals. In addition, the way modern food animals are bred, fed, and housed specifically results in a large number of “production-associated” diseases and deformities. Such maladies are too numerous to list in detail, but representative examples include mastitis, ketosis, abscesses, and lameness in dairy cattle; feedlot bloat and abscesses in beef cattle; lameness, feather-pecking, respiratory problems, sudden death, and broken bones in poultry; and musculoskeletal problems and tail-biting in pigs (Singer 2002; Singer and Mason 2006; Rollin 2009; Foer 2009).

Poultry, pigs, veal calves, and many cattle may be kept in such close confinement that they cannot walk or even turn around, as exemplified by gestation crates, veal crates, battery cages, and tie stalls. Often the animals are kept in barren environments, on uncomfortable surfaces (e.g., hard, slatted floors), and lack environmental enrichment or opportunities for socialization. This close confinement prevents the animals from satisfying most if not all of their preferences and is associated with physical discomfort, injury, and mental distress. Because close confinement and the continual disruption of social groups lead to in-fighting among animals, pigs’ tails and a portion of birds’ beaks will be often cut off to prevent biting and pecking. This is typically done without anesthesia and may cause lasting pain or difficulty eating (Singer 2002; Singer and Mason 2006; Pew 2008; Foer 2009).

The US Humane Methods of Slaughter Act requires stunning of food animals prior to bleeding, skinning, and dismemberment, but does not apply to poultry, who are conscious during the slaughter process (Humane Methods of Slaughter Act). Both the US government and eyewitness accounts of slaughterhouse practices indicate that the Humane Slaughter Act is inadequately enforced (GAO 2010; Foer 2009). Animals may be scalded, skinned, or dismembered while partly or fully conscious. Other sadistic abuses at

slaughterhouses, such as ramming animals with forklifts, beating them with pipes, chasing them into scalding tanks, stomping on them, or holding electric prods in their eyes, have been documented and do not appear to be rare, perhaps resulting from the stressful workplace environment for slaughterhouse workers and the dehumanizing nature of the work (Foer 2009).

Finally, IFAP presents infectious disease risks to the public. Between 60% and 80% of total antibiotic production in the United States goes to animal agriculture, with much of this representing nontherapeutic use for growth promotion (Mellon et al. 2001). Antimicrobial use in agriculture has been closely linked with the emergence of antimicrobial-resistant (AMR) strains of multiple species of bacteria; some of these antimicrobials are critical to human health. Overall, antimicrobial resistance is a serious public health problem, accounting for many emerging infections worldwide, and is associated with increased morbidity and mortality, billions of dollars in additional healthcare costs, and longer hospital stays (Pew 2008).

Furthermore, IFAP creates risks for zoonotic disease transmission, the most significant being the risk of a pandemic influenza outbreak. Both poultry and swine carry influenza viruses, the spread and mutation of which are facilitated by the close crowding of animals in CAFOs. Mutated strains of these viruses could cause a pandemic among humans, and indeed there is reason to think that this is a reasonable probability. A 2009 influenza pandemic was of swine origin, and the 1918 “Spanish Flu,” which may have killed as many as 100 million people, is thought to be partially or wholly of animal origin. Certain highly pathogenic strains of avian influenza can infect humans, and though such strains are not highly infectious at present, this could easily change (Greger 2006; Neumann et al. 2009).

Existing Critiques of IFAP

Moral critiques of IFAP and/or animal agriculture in general have been made from a variety of normative theoretical perspectives, including

utilitarianism (e.g., Singer 1980, 1993; Singer and Mason 2006), rights theory (e.g., Regan 2001, 1983/2004), coherentism/common morality (e.g., DeGrazia 1996), and a feminist ethic of care (e.g., Donovan 1990/ 2007). To date, many if not most developed philosophical critiques of IFAP have focused on human obligations to animals and the ways in which IFAP violates these obligations. However, many of these critiques, as well as nonphilosophical reports on IFAP (e.g., Pew 2008), also emphasize the negative environmental and human health impacts of IFAP without necessarily locating these impacts within a specific moral framework, theory, or argument.

Peter Singer provided one of the first and most famous critiques of IFAP in his book *Animal Liberation* (Singer 1975/ 2002). Though Singer is a utilitarian, the argument that he presents in this work is based more on the common morality than on explicit utilitarian calculations. Singer argues for a principle of equal moral consideration of interests (EC), which requires that we recognize a similar presumption against causing a certain amount of animal suffering as we would a like amount of human suffering. He arrives at this conclusion based on the rejection of species or mental capacity as relevant criteria for morally “discounting” animals’ interests. As concerns farm animals, he devotes a chapter to arguing for the conclusion that, in modern IFAP systems, “these animals live miserable lives from birth to slaughter” (Singer 1975/2002, p. 97). Given an implicit presumption of nonmaleficence against humans, this empirical conclusion, coupled with a principle of equal consideration, secures the moral conclusion that IFAP is indefensible.

In multiple works, David DeGrazia (1996) extends Singer’s common-morality approach. DeGrazia, too, argues for a principle of equal moral consideration of interests, building upon the arguments Singer presents, but overall presenting a more philosophically developed and rigorous defense of equal moral consideration. Like Singer, DeGrazia argues that IFAP causes tremendous animal suffering, that sentient animals and humans possess a relevantly similar interest in not suffering, and that our common morality strongly endorses a principle of

nonmaleficence, thus yielding the conclusion that IFAP is morally indefensible. However, DeGrazia strengthens this nonmaleficence-based case against IFAP as compared to Singer by arguing that confinement and death, and not just suffering, are harms to animals.

While multiple philosophers have presented compelling cases for a principle of EC, many persons will still not accept this view, and furthermore the philosophical case for EC is not indisputable. Therefore it is significant that a rejection of IFAP on animal welfare grounds need not rest upon this principle. Elsewhere, DeGrazia (2009) and Garner (2005) have argued that we only need acknowledge that animals have nontrivial moral status in order to reject IFAP, not that we need acknowledge EC or even unequal but substantial moral consideration. This conclusion is based on a specification of nonmaleficence so as to be consistent with even the weak anticruelty ethic currently predominant in Western society, thus holding that “we should not cause massive, non-consensual harm to animals for unimportant human purposes.”

Not only is it argued that the consumption of animal products per se is an unimportant human interest, given that plant foods can provide adequate nutrition and also be palate pleasing, but in addition the rejection of IFAP-derived animal products (on the argument presently considered) does not rule out the consumption of animal products from nonindustrialized agricultural systems. Here the human interest at stake is perhaps a modest additional cost for such products and perhaps also some minor inconvenience in having to locate animal products from ethically defensible sources and/or to abstain from eating animal products when non-IFAP-derived products are not available. This seems to be an even less significant interest than the interest at stake in avoiding animal products entirely.

A number of moral theorists have explicitly defended the rights of animals. To say that animals have rights is not to say which rights they have. It is conceptually possible to acknowledge very limited animal rights in a way that is consistent with the prevailing (or emerging) social ethic (e.g., the right to be spared pain and suffering in the service

of trivial human goals), but as discussed above even these minimal rights seem sufficient to reject the defensibility of IFAP. Some philosophers, such as Tom Regan (1983/ 2004), Evelyn Pluhar (1995), and Mark Rowlands (Rowlands 2002), have argued for more robust animal rights, based on inherent value (Regan), a principle of rational altruism (Pluhar), or an amended version of Rawlsian contractarianism (Rowlands), coupled with a principle of EC covering all animals with desires or a welfare (which certainly includes farm animals). These rights typically include strong negative rights against the imposition of harm and the restriction of liberty and so would rule out most (perhaps all) animal agriculture and not just IFAP. While rights views and coherentist/common-morality views may sometimes part ways in normative justification (e.g., as concerns the sacrifice of one individual to prevent the death of many), as concerns IFAP these two approaches look very similar when based on a principle of EC.

Utilitarian critiques of IFAP have also been published (e.g., Singer 1980, 1993). These critiques typically emphasize that the harm perpetrated upon animals in IFAP systems greatly outweighs any benefit to humans such systems provide, including the benefits of employment and the pleasurable taste of animal flesh. These critiques often compare the human interest in eating animal products with the human interest in eating plant products, noting that plant-based foods can be both tasty and nutritious and that any loss in utility incurred by depriving people of desired animal foods would be relatively small and greatly outweighed by the ending of animal suffering.

However, if the question at hand is the moral defensibility of IFAP as compared also to extensive animal agricultural systems, then again the significance of the human interest being sacrificed is even lesser. Furthermore, since extensive farming systems require more labor inputs and more husbandry expertise than intensive farming systems, the transition from IFAP to extensive animal agriculture may actually *create* jobs. The switch from IFAP systems to extensive animal agriculture would also likely entail a decrease in per capita meat consumption in developed countries,

which would have health benefits for such persons (see Garrett 2007). Finally, switching from IFAP systems to extensive animal agricultural systems would decrease environmental pollution, increase the quality of life in rural communities, and decrease the risk of an influenza pandemic, further strengthening the utilitarian argument against IFAP.

The utilitarian case for vegetarianism is slightly less clear but still strong. Singer (1993, pp. 132–133; see also Singer and Mason 2006) argues that non-self-conscious animals do not have a preference interest in staying alive, that it is morally unproblematic to painlessly kill animals that have lived happy lives and replace them with other animals leading equally happy lives (the so-called replacement argument), and that, since such happy animals would not be brought into existence except to be eaten, utilitarianism may identify an extensive animal agricultural system providing for excellent animal welfare as the moral ideal. This is a controversial argument, but even if it is accepted, a utilitarian can recognize other reasons for moving towards a plant-based agricultural system, some of which Singer himself provides.

First, there is a slippery slope objection: if it is accepted that it is morally legitimate to kill animals for food – a trivial purpose when not necessary – then we will come to view them as objects to use as we please. In the face of ever-present market pressure for greater efficiency and lower cost, this attitude is likely to result in backsliding into industrialized agricultural systems (Singer 2002, p. 134). Second, it has been argued that as compared to a pasture-based animal agricultural system, a plant-based agricultural system would allow a greater number of animals to live happy lives, since a plant-based system would kill fewer animals and also allow land to revert to the wild state, thereby supporting wild animals that would not otherwise exist. Furthermore, it is argued that the welfare of animals accidentally killed in plant-based agriculture (e.g., by tractors) is overall better than the welfare of even extensively raised animals (Matheny 2003).

Third, since a plant-based agricultural system would allow an additional 840 million persons to

be fed, there is (assuming appropriate distribution) an immense utility gain from this (see Pimentel and Pimentel 2003; Singer 1980). Finally, given the apparent health benefits of plant-based diets as compared to animal diets, it may be the case that population health would be maximized if everyone followed a plant-based diet, further increasing utility (Garrett 2007).

Finally, a number of feminist scholars have argued for either moral vegetarianism or a non-industrialized animal agriculture that provides for better animal welfare than IFAP. Though there is diversity within feminist ethics, these conclusions generally seem to be reached through the advocacy of an “ethic of care,” one which is contextualist rather than universalist, one which emphasizes personal relationships and responsibility over impersonal rights and obligations, and one which “requires a fundamental respect for nonhuman life-forms, an ethic that listens to and accepts the diversity of environmental voices and the validity of their realities” (Donovan 1990/2007, p. 75). Donovan asserts that “feminists must reject carnivorousism” (1990/2007, p. 76), a conclusion also supported by some other feminist scholars (e.g., Gruen 2004/2007). However, still other scholars accept the basic commitments of an ethic of care as sketched here, reject IFAP, but defend some consumption of meat and other animal products (George 1994). Nonetheless, most feminist scholars who write about animal ethics appear to be critical of IFAP.

New Directions for Critiquing IFAP

With the exception of utilitarian critiques, existing philosophical critiques of IFAP tend to focus on animal welfare, but as discussed in this essay, the negative effects of IFAP extend far beyond this. Hence a future direction for critiques of IFAP is to build these other negative effects into non-consequentialist philosophical critiques in a more developed way. Of course, a person could simply argue that we ought not to act when so acting brings about significant, bad consequences for the environment, for animals, and for present and future humans and where the action in

question serves only to satisfy a trivial human interest. This argument seems plausible enough, but philosophers may press the critic of IFAP to address a number of philosophical issues, such as the distinction between intending and foreseeing harm, the distinction between acts and omissions, our moral obligations to future generations, and the intrinsic value of the environment. These issues cannot be pursued in detail here, but a few brief observations are noted.

First, human obligations to protect and preserve the environment might be accounted for by acknowledging and defending a human right to health, insofar as an unspoiled environment (however this is understood) is a necessary precondition for human health. Such an argument can be extended to critique IFAP, given IFAP's substantial contributions to environmental pollution and global climate change (Brei 2012). Second, biocentric theories that intrinsically value non-sentient individuals, species, and/or ecosystems (e.g., Varner 1998) also contain ample resources to reject IFAP. Notably, though it is sometimes held that biocentric theories are incompatible with individualistic theories, this need not be true: a person may acknowledge the value of sentient individuals as well as non-sentient individuals and wholes, such as species or ecosystems (Varner 1998; Jamieson 2003). Hence the recognition that the environment has intrinsic value can strengthen existing cases against IFAP, instead of being thought of as grounding an alternative case.

Third, a good case can be made for recognizing our obligations to future generations, and though establishing this leaves open the content of such obligations, IFAP's negative effects as concerns the environment, food abundance, and zoonotic disease are arguably significant enough to circumvent controversies regarding the strength of our obligations to future persons. If we have any obligations to future persons whatsoever, then arguably these would at minimum include obligations not to impose significant harm or risk upon them in order to serve the trivial interests of presently existing humans or to leave them a world in which they have a significantly harder time meeting their basic needs as compared to alternatives. Given world population growth and expected food

demands, the threat of global climate change, worsening water shortages, and the increasingly concerning risk of a global influenza pandemic, it can be argued that IFAP's continuation would lead to exactly these consequences.

Defenses of IFAP

Just as striking as the many possible philosophical routes by which one might criticize IFAP is the lack of defenses offered for it. Some philosophers have questioned whether utilitarian commitments lead necessarily to vegetarianism (Frey 1983; Regan 1983/ 2004), but strictly speaking this is not an argument in defense of IFAP; even utilitarians who defend animal agriculture typically reject IFAP (see, e.g., Frey 1983). (In addition, arguments undermining a utilitarian commitment to vegetarianism may fail in their own right.) Some other philosophers who argue that animals have little or no moral status (e.g., Leahy 1993) seem to suggest that IFAP is not morally defensible. Wesley Smith offers one of the few defenses of IFAP specifically that can be found in the published literature (Smith 2010). Smith's argument draws heavily from Carl Cohen (see Cohen 2001), who argues that animals do not have rights, but that humans have significant obligations to treat animals humanely; Cohen does not apply his arguments to agriculture, but Smith does. However, neither author has much to say about the content of our obligations to animals, and it is arguable that "humane" treatment is inconsistent with IFAP. (Cohen's argument is also vulnerable to a number of other criticisms; see Regan 2001 and Nobis 2004 for discussion.)

Furthermore, Smith's defense of IFAP specifically – as opposed to animal agriculture more broadly – is that it supplies cheap food to poor persons. This presumes, perhaps erroneously, that plant-based diets are significantly more expensive than animal-based diets; as already discussed, some studies suggest that such cost differences may be minimal. It also ignores the role that externalized costs (e.g., grain subsidies, environmental pollution) play in creating an artificially low market price for animal

products. Moreover, though Smith defends human exceptionalism, his argument in favor of IFAP ignores the other costs that it imposes on present and future *humans*. Finally, given the other ethical objections that can be raised against IFAP, it seems wrongheaded to perpetuate it just to provide food for persons who otherwise cannot afford it. Presumably better options are available to satisfy this admittedly important goal, for example, ending grain subsidies and using such monies to directly subsidize food assistance programs.

Finally, the animal agricultural industry and organized veterinary medicine often fiercely defend IFAP from its critics, but for a variety of reasons, the arguments they typically make are problematic. First, these groups often commit themselves to highly contentious (if not dubious) claims, such as the claim that we lack sufficient evidence to causally link antimicrobial use in agriculture to antimicrobial resistance in human populations or the claim that intensive confinement is not detrimental to animals' welfare as compared to alternative housing systems (American Veterinary Medical Association AVMA 2005, 2009). Second, these groups often ignore or downplay some of IFAP's costs, such as its contributions to environmental pollution or global climate change. Third, these groups often emphasize that IFAP provides a safe, abundant, and inexpensive food supply (AVMA 2008; Animal Agriculture Alliance). However, some evidence suggests IFAP actually compromises food safety, and there is a lack of compelling reasons to think that alternative agricultural systems will produce an unsafe or less safe food supply (Pew 2008; Foer 2009).

As concerns food abundance, IFAP produces less food overall than a plant-based agricultural system or an agricultural system where animals are only pastured on lands unsuitable for crop production. The significance of IFAP's production of cheap animal products has already been discussed. Finally, these groups often make ad hominem attacks against their opponents, such as dismissing calls for more space for farm animals as "arbitrary and emotion based" (AVMA 2008). They may also respond disingenuously to

criticisms, for example, by arguing that farm-animal housing is "species-appropriate" when responding to the criticism that farm animals are not provided enough space to move around (Animal Agriculture Alliance). These tactics raise concerns about bias and credibility.

Summary

Significant evidence supports the conclusions that industrial farm-animal production is highly detrimental to animal welfare; contributes substantially to anthropogenic greenhouse gas emissions, environmental pollution, and the risk of zoonotic disease; lowers the quality of life in rural communities; lowers the overall amount of food available as compared to alternative agricultural systems; and promotes a diet rich in animal products that is detrimental to the public's health. Moreover, IFAP can be and has been critiqued from a variety of normative ethical perspectives, while arguments defending IFAP are both infrequently encountered and vulnerable to significant criticism. The conclusion that IFAP is morally indefensible appears overdetermined.

Introduction

Following domestication approximately 10,000 years ago, the small-scale slaughter of animals for human consumption was performed on farms, in butcher shops, and even openly on city streets.

This began to change in the Western world in the nineteenth century. Increased urbanization, a growing demand for meat, and an increasing concern over public hygiene, along with a distaste for the sights, sounds, and smells of slaughter, led to the concentration of slaughter practices in public slaughterhouses (e.g., Fitzgerald 2010). The first public slaughterhouse opened in 1818 in Paris became a model quickly emulated across Europe.

Slaughter methods and practices used in these early slaughterhouses were primarily based on practicalities. For example, to prevent worker injury, cattle were restrained and immobilized with a blow to the head (typically from a poleax) before being bled out.

However, public concern for the welfare of animals increased, particularly during the development of the humanitarian movement, with the influence of philosophers such as Jeremy Bentham, who submitted that animals may be sentient (capable of experiencing pain). This led to the development of societies for the protection of animals – most notably, the SPCA, created in England in 1824 (now known as the RSPCA) – and the search for methods of stunning that would render animals unconscious before butchering. Several such methods, developed during the latest part of the nineteenth century, included the use of electricity, carbon dioxide, and slaughter masks applied to the head of the animals to allegedly facilitate the accurate delivery of the stunning blow (MacLachlan 2008).

While butchering processes inside these early slaughterhouses remained largely unchanged, the Chicago Stockyard slaughterhouse, which opened in 1865 in the United States, developed industrial processes to increase productivity (Fitzgerald 2010). These processes included the compartmentalization of the butchering process with workers given specific, repetitive tasks. Industrialization considerably increased the number of animals

that could be slaughtered, famously documented in Upton Sinclair's 1906 novel *The Jungle*. Sinclair described the disturbing effects the industrialized slaughterhouses had not only on the workers but also on the animals.

Today, industrialized slaughter methods govern the killing of animals by the meat, dairy, and egg industries in the Western world, where the vast majority of animals are increasingly killed in relatively few, large-scale slaughterhouses owned and operated by large-scale corporations. In Canada, for example, two massive, privately owned slaughterhouses in Alberta now account for the killing of nearly 90% of the country's 5½ million cattle.

National slaughter regulations seek to minimize the pain and suffering of animals during slaughter. In addition, the Animal Health Organization (OIE) sets international standards for the transport, handling, and slaughter of farmed animals. These regulations and standards determine which slaughter methods are acceptable and typically include a requirement to immediately stun animals before slaughter to render them unconscious.

Animal welfare research, however, suggests that these regulations and standards may not be sufficient to protect animals at the time of slaughter, particularly in modern industrialized slaughterhouses with high line speed and worker turnover rates. In addition, some species may be excluded from protection (e.g., chickens, turkeys, ducks, and geese in the United States); ritual halal or shechita (kosher) slaughter methods, which are traditionally performed without stunning, are also often excluded. In these cases, loss of consciousness and death do not occur immediately and, therefore, are likely to cause fear, pain, and distress in animals. However, even when stunning is performed, fast-paced conditions may contribute to the cruelty routinely documented in slaughterhouses.

Killing with Prior Stunning

Most animal slaughter regulations dictate that all animals, except those killed according to halal or

kosher standards, be rendered unconscious before being killed. Stunning, done by concussion, electrocution, or gassing, aims to render animals unconscious or insensitive to pain. Sticking, done by cutting the animals' throat horizontally or severing the major blood vessels arising from the heart, brings about death by exsanguination (OIE 2012). Animals are then skinned, disemboweled, and dismembered.

Regulations stipulate that to reduce pain and distress, loss of consciousness must occur immediately after stunning, and bleeding must cause death without risk of animals regaining consciousness. However, ineffective stunning and sticking procedures are common and can cause animals to experience fear, pain, and suffering.

Percussion Stunning and Animal Welfare

The purpose of percussion stunning is to cause head trauma with (or without) penetration of the brain. Penetrating percussion stunning is achieved through gunshot (most frequently, a 22-caliber free bullet) or penetrating captive-bolt devices, which fire a metal rod through the brain via a blank cartridge or pressurized air. The device is routinely used to stun cattle, goats, horses, sheep, and pigs. Non-penetrating, or mushroom-shaped, captive-bolt devices are used on cattle in addition to small animals like rabbits. These devices work by striking the animals' head with a non-penetrating bolt, causing concussion as a result of the impact. Unlike the penetrating devices that damage the brain, non-penetrating devices cause temporary loss of consciousness, which can be reversed.

For percussion stunning to be effective, impact to the brain must occur in the area responsible for consciousness, the precise positioning of which varies between species. It also must have sufficient velocity to bring about concussion and loss of consciousness. In industrial slaughter with its focus on line speed, one or both of these requirements may not be fulfilled.

The effective stun spot within an animals' skull makes for a small target, and thus accurate placement of the stunning device or gunshot is critical. In large slaughter plants where line speed is fast and several hundred animals may be stunned per

hour, the risk of mistakes and misplacement of the shots is high, particularly when fearful and trembling animals move or thrash about in an effort to avoid the weapon. These problems are compounded when workers are not properly trained or fatigued from long hours and redundant tasks.

Additionally, equipment failure presents a significant problem. During high line speed, penetrating captive-bolt devices may be used repeatedly before being cleaned. Multiple problems can occur as a result: the device may become jammed with brain matter and skull fragments, preventing the bolt from discharging or reducing the target accuracy and velocity. The fast-paced consecutive shots delivered by a penetrating, cartridge-powered stunning device produce heat, which may decrease the energy or velocity of the strike (Gregory 2008). In these cases, the failure to strike, loss in strike strength, and/or loss in strike velocity is likely to cause improper stunning. More than one shot may thus be required to stun the animals, and this may not be delivered due to high line speed.

After stunning, animals are shackled, hoisted by one hind leg, and moved to a bleeding area where their throats are partially cut. Animals who are improperly stunned, or who regain sensibility, experience a high degree of pain and fear during exsanguination. Incomplete or misplaced sticking prolongs the time required for sufficient bleed out to cause cerebral death, causing still-conscious animals to be suspended, bled out, and butchered. In her book *Slaughterhouse*, Gail Eisnitz, who conducted and compiled interviews with American slaughterhouse workers, reports that animals routinely exhibit signs of consciousness, such as blinking, kicking, or shrieking, during the butchering process.

Electrical Stunning and Animal Welfare

Birds

Electrical stunning, or electronarcosis, is commonly used to stun birds (chickens, turkeys, ducks, and geese). While handheld electrical tongs applied to the head of each animal may be

used, this method is not practical in slaughter plants processing tens of thousands of birds a day. In these facilities, birds are instead shackled upside down by their feet on a moving rail to have their heads dragged through a water bath stunning system. Many welfare issues are tied to the use of these systems.

Prior to stunning, birds are at risk of receiving painful pre-stun shocks if splashed before being submerged or if the tips of their wings dip into the electrified water – a problem particularly common with turkeys as their wings hang lower than the heads, but also frequent with broiler chickens. A recent study found that pre-stun shocks significantly affect meat quality by causing burns to the birds' wing tips, fractures to their breastbones, and bleeding in their wings, shoulders, and breasts (Rao et al. 2013). Panicked birds who raise their heads or attempt to raise themselves are at high risk of missing the stun bath completely.

Improper or ineffective stunning can also occur even with birds whose heads are properly submerged in the electrified water bath. The waveform and frequency of the current, how much the animals are subjected to, and each bird's resistance determines the efficiency and duration of the stun. For instance, low current frequencies (50–60 Hz) may induce fibrillation of the heart (cardiac arrest) and cause death. By contrast, higher frequencies may only momentarily disrupt brain activity in what can be compared to an epileptic seizure and therefore must be applied for a longer period of time in order to induce proper stunning. It should be noted that in most slaughterhouses today, electricity is used only to stun the animals, not kill them. Birds who are effectively stunned may still recover before fully bleeding out.

Research indicates that the voltage required to achieve an effective stun must be a minimum of 120 mA per bird and that currents under 75 mA per bird should never be used (Gregory and Wotton 1990). High voltage, however, is costly and has been linked to meat quality issues, such as broken bones, broken capillaries, and blood spots. Because of this, most slaughterhouses deliberately keep voltage levels low, gaining in meat quality but greatly sacrificing animal welfare.

The problem can be amplified in slaughterhouses that stun birds of differing sizes and characteristics together in multi-bird stun baths as they may have different tolerances to electricity. While some birds may present physical signs of consciousness, others may be indiscernible as improper stunning can result in the paralysis of muscles.

After stunning, the birds have their necks cut, either by automatic spinning blades or manually by workers. Un-stunned birds, and those who have regained consciousness, continue to move by lifting their heads or flapping their wings. As a result, their neck may be only partially severed, or not severed at all, by the blades.

The length of time required for bleed out is dependent on the effectiveness of the cut and whether both carotid arteries are cut. Failure to cut both arteries can add up to 2 min to the time needed for brain failure to occur; severance of only one carotid can leave the birds conscious and suffering for up to 8 min (Gregory 1984). Birds that fail to properly exsanguinate are plunged into the scalding defeathering tank before breathing has stopped. These birds are scalded or drown to death, their blood vessels bursting, turning their skin bright red (referred to as “red skins” or “cherries” by the meat industry).

As a result of these myriad welfare issues, the government of the Netherlands has set proscriptive regulations around the use of the electrified stun bath for birds. Because of this, most poultry slaughterhouses in the country have converted to gas stunning or killing of the birds. Regardless, electrified stunning continues to be the primary means of stunning birds in most industrialized slaughterhouses.

Mammals

Electronarcosis as a stunning method is also frequently used on mammals (pigs, sheep, and calves, in particular). In the case of pigs and sheep, an electrical current is manually applied through handheld tongs by placing the paddles on each side of the animal’s head (“head stunning”) to induce a seizure which disrupts brain function and brings about insensibility. The process, however, is reversible.

“Stun kill” can also be performed by applying one paddle on the animal’s head and the other over the animal’s heart (“head to heart stunning”). Head to heart stunning causes electricity to pass through both the brain and heart, leading to both stunning and cardiac arrest, killing the animal. Head to heart stunning is thus preferable from an animal welfare perspective, but because it can lead to carcass damage is typically ignored in favor of head stunning.

As with birds, a major welfare concern with this form of electrical stunning is the risk of failing to deliver a current high enough to ensure proper stunning. This risk is significant when animals are stunned in groups and voltage is lowered to ensure the safety of the workers. A higher voltage may be used when animals are brought to the stun operator by a conveyor system which restrains their movements; however, even an adequate current does not necessarily ensure a proper stun. If the tongs are applied while the current is flowing or if they are improperly applied, the animals may be subjected to painful electrical shocks. These animals may become paralyzed, but remain conscious, or they may be stunned but regain consciousness.

An additional concern is the short duration of the stunning effect, even for properly stunned animals. Following seizure, pigs and sheep can regain consciousness in just 30–60 s. Often, the time to irreversible loss of consciousness by bleeding is longer than the duration of insensibility produced by stunning. This means that to ensure a less painful death, the animals must be stunned, shackled, stuck, and have bled to the point of irreversible brain death before stunning wears off and the animal regains consciousness. This requirement for prompt actions might not be easily realized, even in the most industrialized of slaughterhouses.

Gas Stunning and Animal Welfare

Gas stunning may help minimize some of the stress associated with handling. Many gas stunning systems for chickens are designed such that birds enter the gas chamber in their transport crates, thus obviating the need for unloading and live hanging. Handling can also be improved for

pigs as most gas stunning or killing systems allow the animals to be moved as a group into the gas chamber. Insensitivity, however, may take longer than with other stunning methods, thus causing longer periods of distress, depending on the gas and concentration used.

Gas stunning is conducted either with a high concentration of carbon dioxide, or with inert gases (argon or nitrogen, in particular), or a combination of carbon dioxide and inert gas. Animals react differently to different gases and concentrations. Birds and mammals react aversively to high concentrations of carbon dioxide as chemical receptors in their brains recognize overabundance of the gas, triggering a pain response and suffocation. In birds, this presents as wing flapping, convulsing, gasping, neck stretching, or head shaking, which often lead to broken wings and blood spots. Pigs' responses include hyperventilation, intense vocalization, and escape attempts.

In an effort to reduce losses from meat damage, some chicken and turkey slaughterhouses first introduce birds to lower levels of carbon dioxide. Observers of such systems, however, have reported the same aversive behaviors when the birds reach the higher concentration of carbon dioxide. The level of the birds' consciousness in these low to high systems remains unclear.

The use of inert gases, however, alone or mixed with low carbon dioxide concentrations, appears to provide some improvements from both animal welfare and meat quality perspectives. These gases are not recognized by chemical receptors in the brains of birds and mammals, and thus the states of anoxia (lack of oxygen) or hypoxia (low levels of oxygen) are not experienced as painful.

Dr. Mohan Raj, a veterinary scientist at Bristol University, conducted experiments which indicate that the use of inert gas (argon or nitrogen), or a mixture of carbon dioxide with inert gas, effectively stunned birds and pigs without causing distress to the animals. In one experiment, pigs entered and reentered a chamber filled with a mixture of argon and carbon dioxide to look for apples. These animals lost consciousness while eating without presenting any stress behaviors (Raj and Gregory 1995). Studies with chickens

and turkeys have similar results: the process causes no sign of respiratory discomfort or other signs of distress (Raj 1996), eliminating the incidence of broken bones, bruises, and hemorrhages. When using a mixture of inert gas with less than 2% residual oxygen, animals are irreversibly stunned in what is known as controlled atmosphere killing (CAK), eliminating the risk of recovery during bleed out.

In most slaughter plants using gas stunning, however, carbon dioxide alone is the method of choice. Reasons cited include prohibitive cost and reduced availability of inert gases, as well as worker safety concerns prevailing over animal welfare considerations.

As a result, animals stunned through gassing typically experience protracted pain before loss of consciousness is achieved, the duration of which varies between individuals. Therefore, in large commercial slaughterhouses, it is impossible to ensure all animals leaving the gas chamber are properly stunned.

Killing Without Prior Stunning

While the majority of modern industrial slaughter plants use a two-step stunning and killing process to slaughter animals for food, halal and shechita slaughterhouses (which kill according to Muslim and Jewish laws, respectively) kill animals by slicing the throat through a single incision without prior stunning. Defenders of halal and shechita slaughter state that the process is humane, claiming it is fast and that the single incision does not cause acute pain. Both statements, however, are debatable.

Brain function does not immediately cease following a cut to the throat. The time required to lose consciousness through bleed out may take up to 2 min for cattle. In addition, a "ballooning" mechanism may occur where blood clots form at the severed ends of the carotid arteries (Gregory et al. 2008). These clots obstruct blood flow, slowing blood loss from the brain and extending the length of time required for animals to lose sensibility. Depending on the location of the cut, loss of consciousness might occur only after several minutes.

The cut itself is also likely to cause pain and suffering. The presence of pain receptors in the area of the cut suggests that throat incisions can “result in very significant pain and distress in the period before insensibility supervenes” (FAWC 2003). In addition, animals may experience fear and panic as they consciously choke to death, aspirating blood into their lungs and respiratory tracts in an effort to breathe (AHAW 2004).

Concerns about animal welfare during slaughter have led countries such as the Netherlands, Norway, Switzerland, and Sweden to ban killing without prior stunning. While such decisions are often criticized, some religious authorities have proposed that stunning animals does not contradict religious precepts. Imam Al-Hafiz Masri, for instance, argues in his book *Animals in Islam* (Al-Hafiz Masri 1989) that the volume of blood draining out of the body after an animal has been stunned is no smaller than the volume of blood draining from un-stunned animals – one of the main beliefs impeding the implementation of stunning in halal slaughter.

The welfare concerns surrounding ritual killing continue to gain exposure as meat and poultry not labeled as halal or kosher are increasingly shown to derive from animals that have not been stunned prior to slaughter. It is believed commercial factors may be responsible as abattoirs without stunning facilities may be less expensive to run. Thus secular consumers, believing they are buying meat from animals who were stunned before being stabbed and bled out, may be supporting a practice they otherwise would not.

Fish

Fish have traditionally been killed by asphyxiation after being removed from water, but with the recent rise in factory farming of the animals, they are increasingly being killed in other ways, with or without prior stunning (Yue n.a.).

Fish (salmon, in particular) may be stunned manually via a blow to the head with a club or “priest.” As with concussion stunning of mammals, the blow must be positioned correctly and done with enough force to ensure proper stunning,

which is often difficult with moving fish and when repeating the action over a period of time. The use of mechanical percussive systems addresses the problem of workers’ fatigue and provides a more consistent blow, but cannot ensure that all animals, particularly those with nonstandard sizes, be properly stunned.

Electrical or gas stunning may also be used. As with birds and mammals, electronarcosis can be ineffective, producing effects unlikely to last long enough to prevent fish from regaining consciousness before they bleed out to the point of insensibility (Benson 2004). Fish subjected to gas stunning show aversive behavior when exposed to high levels of carbon dioxide in the form of hyperactivity, leading to injuries (Yue n.a.). With both electrical and gas stunning therefore, fish may be subjected to distress and possibly pain for several minutes before losing consciousness.

Killing by exsanguination without prior stunning may be performed. In this case, fish, which have their gills or tail blood vessels cut or their heart perforated, are left to bleed before further processing. Inaccurate cutting can be prevented by the fish movements, prolonging the duration of the bleeding and delaying the loss of consciousness.

Finally, some fish slaughterhouses may butcher and process fish without any attempt at rendering them unconscious. This practice was exposed in a Mercy For Animals investigation in Texas in 2010, where catfish were cut into, skinned, suffocated, and dismembered while fully conscious (<http://www.mercyforanimals.org/fish/>).

Worker-Inflicted Cruelty

A number of studies have shown that the work of killing animals in an industrialized system may have social and psychological consequences for workers (e.g., Fitzgerald et al. 2009). The intensive, production-based nature of slaughterhouses forces workers to suppress natural feelings of empathy, desensitizing them to the fear and pain of animals. Numerous documented cases of malicious and intentional cruelty at slaughterhouses

have been exposed by animal advocacy organizations worldwide. These include the beating, stomping, throwing, dragging, electrocuting, stabbing, mis-shooting, and mutilation of fully conscious animals.

While it is impossible to quantify the extent of animal abuse in slaughterhouses, conservative estimates by University of Colorado professor of animal science Dr. Temple Grandin indicate that “only about 20% of animal slaughter facilities operate within acceptable humane guidelines and the rest slip into bad practices, with a full 10% intentionally treating animals cruelly” (2011 Summit of the Horse, Las Vegas).

Summary

Food safety concerns, as well as urbanization and increased consumption of animal products, led to the mass concentration of killing of animals in large, industrialized slaughterhouses in the Western world.

The so-called humane regulations attempt to minimize the pain and suffering experienced by animals during slaughter, yet numerous deficiencies exist. In particular, ineffective or improper stunning is common in all forms used: percussion, electrical, and gas and can cause animals to experience fear, pain, and suffering.

Additionally, halal and shechita slaughter are typically performed without stunning; however, the process arguably causes acute and protracted pain and suffering.

Worker-inflicted cruelty is increasing in the public eye, and research has shown that the intensive, production-based nature of slaughterhouses forces workers to suppress natural feelings of empathy, desensitizing them to the fear and pain of animals.

Because of these significant welfare concerns, modern slaughter methods can hardly be considered humane, and their employment should elicit further ethical debate into the mass consumption of meat and its production through industrial slaughter methods.

Introduction

Food studies generally ignore infant and young child feeding practices in favor of adult eating. Human infants are totally dependent on others for their food, and they survive primarily on one food – milk; however, the bioethical issues concerning infant and young child feeding are seldom explored. Food activists usually focus on adult foods, not baby foods; policy makers concerned with food security ignore breastfeeding because breast milk is neither produced agriculturally nor industrially. Because human milk is produced in the bodies of individual women, it is a greater challenge to relate it to global food issues. Infant and young child feeding is also different from adult eating because the person being fed, the baby, is not making the decisions about what, how, and when to feed. The decision on what to feed an infant is not a lifestyle choice dependent on trends and fashions, but one with vital short- and long-term health implications for both mother and baby. This entry examines the ethical, economical, ecological, and health issues implicated in the feeding of human newborns, infants, and young children.

The Ideal Diet

The first nutrients to nourish new humans pass from mothers' blood through the amniotic fluid into the umbilical cord to the fetus before birth. As the fetus floats in the amniotic sac, the surrounding amniotic fluid carries the tastes of the foods consumed by the pregnant woman available to her in the world outside the womb. After birth, babies take in their first foods by mouth. As with all mammals, the product designed to be that first food is colostrum followed by human milk.

Newborns, infants, and young children are at a vulnerable stage of development. They are exposed to harmful bacteria, viruses, and parasites and in their first months of life have few or only weak defenses to fight them. Before birth the unborn child receives protection from the mother's antibodies. Breastfeeding provides not

only the first food but also the first medicine. The antibodies in human milk help protect against diseases, and breastfeeding boosts the maturation of the infant's immune system. As the Deputy Director of UNICEF states "Breastfeeding is a baby's 'first immunization' and the most effective and inexpensive life-saver ever" (UNICEF 2013). Breastfeeding enhances child survival, encourages healthy growth and development, saves on health costs, and is far more economical for the family budget. In addition, breastfeeding increases child spacing, and for many women it is the only method to plan their families when contraception is unavailable, unaffordable, or unacceptable for religious or cultural reasons. Unlike diverse and culturally shaped adult diets, there are universal agreed upon standards about the ideal diet for human infants – human milk. The World Health Organization (WHO) and UNICEF define the standards for ideal infant feeding in the Global Strategy for Infant and Young Child Feeding (2002): babies should receive breast milk exclusively for the first 6 months of life. After 6 months, babies should be introduced to appropriate and adequate complementary foods, with continued breastfeeding for up to 2 years and beyond. Infants have the right to special protection so that they survive, grow, and achieve their "highest attainable standard of health," in order to realize their full potential.

"Children who are exclusively breastfed are 14 times more likely to survive in the first 6 months than non-breastfed children. Starting breastfeeding in the first day after birth can reduce the risk of newborn death by up to 45%" (UNICEF 2013). Unfortunately, despite these evidence-based arguments and the well-documented benefits of breastfeeding worldwide (WHO 2006), "only 39% of children aged less than 6 months were exclusively breastfed in 2012" (UNICEF 2013). This means that only about one third of the 136.7 million babies born annually are exclusively breast-fed for the first 6 months of life. The high rates of child malnutrition in many countries suggest that infant and young child feeding is far from ideal.

History

Throughout human history, women have always had access to alternatives to maternal breast milk, including wet nursing and the use of animal milks served in horn or terra-cotta feeding bottles. However, any alternatives to maternal breastfeeding were universally recognized as dangerous. Animal milks often played an important role in feeding babies, and many European orphanages kept goats for rearing infants. Wet nurses were carefully vetted, on the assumption that the characteristics of the nurse would be transmitted through the breast milk. However, most alternatives to breast milk used in the past were nutritionally inadequate and contributed to high rates of infant mortality (Van Esterik 1989).

In the fifteenth century in Europe, the first books appeared to provide advice on infant feeding, around the topics of breastfeeding, wet nursing, dry nursing or feeding an infant by hand (artificial feeding), and weaning (Spaulding and Welch 1994, p. 8). One authority, writing in 1804, began his advice on preventing childhood disease assuming that many women were not able to breast-feed their own children because of their delicate constitutions, low spirits, hysteric fits, or other nervous disorders; but he later revised his thinking, claiming that "*many mothers will not nurse, few cannot*" (Spaulding and Welch 1994, pp. 16–17). Wet nursing was generally considered the best way to feed an infant if the mother could not or would not breast-feed her child.

It is likely that women were well aware of the child spacing effects of breastfeeding, although social pressure to have large families may also have influenced their infant feeding decisions. Aristocratic women in Britain and France used wet nurses to avoid the child spacing effects of breastfeeding. These women were required to have numerous male descendants to carry on the family name and property. If they did not breast-feed, they became pregnant again much more quickly (cf. Fildes 1986; Spaulding and Welch 1994).

Historically, the difference between commercial breast milk substitutes and other foods has not

always been clearly defined. Semisolid mixtures of grains, often mixed with animal milk or water, were given to infants to replace or supplement breast milk. These mixtures were fed through feeding devices made of horn or ceramic and were difficult to keep clean. It is only in the last century that improvements in commercial breast milk substitutes permitted many infants to survive without human milk.

The first milk-based commercial breast milk substitute was developed by Nestle in 1867. Early milk-based formulas often included cereals and were marketed as foods and not as liquid breast milk substitutes. These proprietary milk products competed alongside condensed and evaporated milks and custom-made preparations around the end of the century. In 1928, Gerber developed and marketed specialty foods for babies such as strained vegetables and fruit. In the 1930s, strained baby foods were sold in patented vacuum-sealed clear glass jars, replacing lead-soldered metal cans. Commercial baby foods, often called “solids,” were frequently used as breast milk substitutes and were given too early, replacing more nutritious breast milk. Since their development, there has been a steady decrease in the age of introduction of solids to infants. In North America, parents often take pride in seeing infants eat commercial baby foods at increasingly early ages. In France, doctors advised giving artichoke purée to infants at the age of 6 weeks to develop their gastronomic discernment – breast milk was thought to be too monotonous and bland!

Over the next 20 years, the use of commercial baby food increased in middle- and upper-income North American homes, where it was used not just to supplement but also to substitute for breast milk. Specialty products such as preterm infant formula were developed in the 1960s. The 1980s saw the development of fortifiers to adapt human milk for low-birth-weight infants for use in intensive care nurseries. Mothers’ own milk is now recognized as the standard of care for premature infants, with pasteurized or fresh donor human milk used when mother’s own milk is not available. More recently, soy-based products have come onto the market, along with follow-on

formulas for older infants. Since 1980, companies have been trying to add components to create the impression of improving infant formula and making it closer to human milk. These include probiotics, which are live bacteria that colonize the infant’s gastrointestinal tract and are said to provide benefits. However, in their review and comment, the Committee on Nutrition of the European and American Societies for Pediatric Gastroenterology, Hepatology and Nutrition states: “At present, there is insufficient data to recommend the routine use of probiotic- and/or prebiotic-supplemented formulae.” The Committee noted: “Because most of the trials were company funded, independent trials, preferentially financed jointly by national/governmental/European Union bodies and other international organisations, would be desirable” (ESPGHAN and NASPGHAN 2011).

Global conditions of food production and distribution have increased households’ access to commercial breast milk substitutes around the world. In spite of breastfeeding protection, support, and promotion efforts by governments and civil society, the sale of commercial breast milk substitutes and baby foods has steadily increased. The global market for baby food is projected to reach USD 63 billion by 2017, after growing from USD 28 billion in 2007 to USD 41 billion in 2012 (2011 Baby Food and Pediatric Nutrition Market).

Ethical Dimensions of Infant Feeding

Infants have no responsibility for the decisions made about how they are fed. Mothers usually bear the brunt of the blame for any infant feeding problems. But society needs to take responsibility to ensure that the next generation is adequately fed and nurtured. It falls on the state to deal with failures when neither families nor communities take responsibility to make sure every child has the best possible start in life. Ideally, then, infant feeding should be guided by collective ethics. This would include the right to factual, unbiased information about breastfeeding, commercial breast milk substitutes, and other methods of infant feeding.

Ethical Complexities of Breastfeeding

Support for breastfeeding mothers should be a matter of public policy, including the right to feed in public without harassment or undue attention. Expecting women to breast-feed without providing the necessary supports, including good maternity entitlements, is unethical. It is ethically responsible to provide mothers with accurate information about breastfeeding, including the existence of chemical residues in their milk, remembering that all living beings carry a body burden of industrial chemicals (IBFAN 2013). Women should not be told that breastfeeding is instinctive, natural, or always problem-free, but be provided with access to the means to solve occasional problems such as mastitis or poor positioning. A few women have difficulties with their milk supply, even with frequent breastfeeding, but as WHO explains: “Exclusive breastfeeding from birth is possible for most women who choose to do so. It is recommended for all children except for a few medical conditions, such as maternal medication and radioactive substances. Exclusive breastfeeding as often and as long as the baby wants results in ample milk production” (WHO/UNICEF 1993; WHO 2006). Ignoring or discounting the difficulties that some Euro-American mother–infant pairs have with breastfeeding may increase the guilt mothers feel when they fail to breast-feed their infants exclusively or bottle-feed in public. This is not the intention of groups who promote breastfeeding, who need to be sensitive to the conditions that make it impossible for some women to breast-feed, such as some breast reduction surgery and active tuberculosis. Since chemotherapy drugs pass through mother’s milk, mothers must make difficult decisions when cancers are discovered during pregnancy. Until recently mothers who were HIV positive were advised not to breast-feed, but recent WHO policy directives acknowledge that exclusive breastfeeding provides the best option for infants of HIV-positive mothers who cannot use commercial infant formulas safely (WHO 2010a, b).

Another ethical dilemma concerns the use of human milk, donated by mothers for sick and premature infants, but sold by companies or used to make products for sale for infant feeding – or to

make exotic items such as ice cream and cheese made from human milk. Recent attempts by commercial companies to patent the constituents of human milk are more sinister. Advocates have petitioned to stop companies from patenting human milk components, many of which use genetic engineering techniques to genetically modify animals or plants to produce human milk components such as lactoferrin (ICDC 2013).

It is unethical to experiment on breastfeeding mother–infant pairs to conduct randomized clinical trials with control groups, when there is already agreement that human milk is best for infants. But without such clinical trials, breastfeeding research is often criticized for being unable to separate the effects of parental behavior from the effects of breastfeeding or the effects of breast milk.

It is important to guard against arguing that if breast milk is good for babies, then it is the mother’s responsibility to provide the milk. Women have prime responsibility for childbearing, birthing, and then caring for, nurturing, and nourishing infants. But to what extent are mothers responsible for decisions they make, given the lack of objective information to make an informed decision, the social pressures and criticism (“your milk is too thin, too bluish, too watery,” etc.), as well as the marketing strategies (“your formula-fed baby will be smarter, have better eyesight, have more developed brain, have whiter skin,” etc.)? It is also important to examine more carefully the role of male medical experts in framing medical knowledge about breastfeeding. Is it unethical for males to tell women they must breast-feed for the sake of their infants while ignoring the expertise of generations of mothers? This question suggests the importance of peer support from experienced breastfeeding mothers.

Ethical Implications of Feeding Breast Milk Substitutes

The regular use of commercial breast milk substitutes or routine artificial feeding instead of maternal breastfeeding constitutes the largest in vivo experiment in human history, yet the risks inherent in the use of these products are

rarely discussed even by health professionals. There is no way to know the full effects of raising human infants without human milk. This is ethically irresponsible and raises questions about what level of risk society is prepared to accept.

Baby food companies have an ethical responsibility to their shareholders and investors to maximize profits and thus shareholder dividends. To accomplish this, companies scale up their product promotions to enlarge and create new markets, increase market share, and boost sales. Their market share increases when fewer mothers breast feed for shorter durations. These industries are in the wealth creation business not the health business. Their behavior is acceptable to many people who argue for regulation-free markets and the right of consumers to choose from a wide range of commercial baby foods. But these companies should have no place in making health policy when prioritizing their profits and dividends may compromise infant health.

The companies (manufacturers and distributors) that manufacture and distribute commercial breast milk substitutes have created these vast global markets by using promotional strategies, such as advertising and discounts, augmented by apparent endorsement by the medical profession. Health professionals need protection against aggressive and subtle promotional practices.

Commercial breast milk substitutes are also far from ideal products, but their risks are not widely known. Bottles of infant formula have to be correctly prepared in hygienic conditions using clean equipment and boiled water. Feeding bottles and teats are extremely difficult to keep clean; feeding bottles, the water used to prepare the feed, as well as the powdered formula itself may be contaminated by harmful bacteria. In addition, infant formula is easily (and often) overdiluted because parents cannot afford the high cost of commercial breast milk substitutes, and this can lead to undernutrition, stunting and wasting, and increased vulnerability to diarrheal and respiratory infections. In the 1978 Kennedy Hearings in the American Senate, this was referred to as “commerciogenic malnutrition.” Drinks with low nutrient value, such as tea, coffee, sugary drinks, and carbonated soda pop, are unsuitable for infants and young

children but have been used inappropriately as breast milk substitutes.

Industrial accidents in the production of infant formulas and baby foods are not uncommon and require costly recalls; recent cases include baby rusks with pesticide traces; plastic and glass shards in jars of baby food and cans of infant formula; cadmium-laced carrots; soy formula labeled as soy but containing cow’s milk; excessive amounts of vitamin D, aluminum, lead, iodine, and melamine; as well as insufficient amounts of other nutrients in infant formula (Ljung et al. 2011).

The Codex Alimentarius Commission, a joint program of the UN World Health Organization (WHO) and the UN Food and Agriculture Organization (FAO), identified harmful bacteria such as species of *Salmonella* and *Cronobacter sakazakii*, formerly known as *Enterobacter sakazakii*, found in unopened tins of powdered infant formula. Recent outbreaks of infections have confirmed that the problem is not always in the mode of preparing and filling bottles, but may be intrinsic to the industrial processing of powdered infant formula itself. Infections caused by these bacteria can be fatal for vulnerable newborns and infants or may cause lifelong disabilities (WHO 2007). The bacteria might enter infants by three routes: first, from the raw materials used in the production of the infant formula; second, from contamination by probiotics or vitamins which are added following pasteurization; and third, during reconstitution.

When soy-based formulas are made from genetically modified soy (GMO soy), concerns have been raised that the arsenic-rich poisons used in the pesticides required for their production, in combination with the phytoestrogens in soy, might increase risks for cancers. Critics of breastfeeding advocacy claim that the risk of using milk- or soy-based infant formula is overblown; *C. sakazakii* and *Salmonella* species are evidence that the risks are real. Efforts to improve infant formula are commendable harm reduction strategies, valuable as long as they are evidence based, not accompanied by health claims, and applicable across the board; that is, if a constituent is found to be useful, it is added to all brands of infant formula, not just one brand.

Product labels are also important to consider, since instead of alerting product users to the risk of intrinsic contamination by harmful bacteria, the baby food industry often tries to make unfounded health and nutrition claims for their products. These claims can be based on misleading and unsubstantiated statements. For example, many brands introduce ingredients such as probiotics derived from animal bacteria. Even company-funded trials show no differences in growth between infants fed with supplemented and non-supplemented products. In fact, it is difficult to know what bacteria are the best probiotics, and “There is insufficient evidence to recommend the addition of probiotics to infant feeds for the prevention of allergic disease or food reactions” (Cochrane Summaries 2009). When research results are provided, they are usually from industry-funded research, another complex ethical dilemma concerning conflicts of interest.

A further risk concerns obesity and over-nutrition; while baby foods and commercial breast milk substitutes can be overfed, even force-fed by hand or bottle, it is impossible to overfeed a breastfed baby. The sugar content of many infant formulas is exceptionally high, and labels carry a bewildering number of different names for types of sugars. Concerns about childhood obesity have drawn researchers to examine television advertising for high-fat, high-sugar snack foods targeting toddlers, since young children cannot always distinguish advertising messages from cartoon characters. Thus, food advertising to young children, both directly and through the food provider, is a subject of ethical complexity. Although direct advertising for infant formula was prohibited under the International Code of Marketing of Breast-Milk Substitutes (WHO 2006), advertisements for infant formula regularly appear on North American television.

Solving Problems: Improving Infant Feeding

In the twentieth century, parents turned to expert authorities to help them feed their infants. The decisions of North American parents were shaped

by advice books such as Dr. Spock’s *The Common Sense Book of Baby and Child Care* (1946), by instructions from the emerging specialty of pediatrics, and by advertising for commercially produced baby foods. However, infant feeding decisions need to be based on objective and up-to-date information from independent unbiased sources; these are not really choices in the sense of choosing between different brands of ordinary consumer products such as ketchup in a supermarket. Legislation is needed to protect baby foods. The cultural perception that artificial infant feeding carries no risks is maintained very effectively by promotional material given to mothers and health professionals.

The development of mass produced baby foods has been profitable, but not problem-free. It is important to protect the growth and development of infants and young children through appropriate policy measures to guarantee the safety of their food. But as Senator Edward Kennedy asked in the opening of the 1978 public hearings in the US Senate:

Whose responsibility is it to control the advertising, marketing and promotional activities which, in and of themselves, may create a market in spite of public health considerations? When economic incentives are in conflict with public health requirements, how shall that conflict be resolved?

One answer is that governments have a duty to fulfill every child’s right to the highest attainable standard of health, as stated in Article 24 (d) of the Convention on the Rights of the Child, the most widely ratified UN Convention in history (UNICEF 1990). Mothers are not mandated to breast-feed, but governments are mandated to provide accurate information about how to attain this high standard of health. This may include education and support from all sectors of society, including information about milk banks and donor milk, a critically important product for premature infants.

In addition, parents and carers bear responsibility for reading the instructions to prepare commercial breast milk substitutes as safely as possible and feed their infant consistently. However, if the product label is in a language that is not used in the region or country or if they cannot

read, are they still responsible? Formulas are expensive and if parents cannot afford the quantities needed to feed their infant and dilute the formula so that it is thin and watery and the baby becomes malnourished, is this also their responsibility?

Although some infants are at severe risk of morbidity and mortality (disease and death) resulting from the use of breast milk substitutes, unlike tobacco, these products are not lethal to a large percentage of their users. There is clearly a need for nutritious and safe formulas based on cow or soy milk for those infants and young children who cannot be breast-fed, including mothers with TB and cancers requiring chemotherapy.

Commercial baby foods are made by companies that are under no ethical obligation to promote child health – a public good. The food industry expects to make profits from the food it produces and markets to the general population, and baby food is no exception. Although many argue that foods for infants and young children should be exempt from market forces, realistically, this is unlikely to happen, considering the profitability of the market for baby foods.

There is no way to ensure safe formula feeding, only safer formula feeding. Advocates for improved infant feeding have been seeking strategies to improve the safety of baby food. These include making the dangers of infant formula more widely known to parents and health professionals, mandatory labels on products to warn that powdered formula is not a sterile product, and explaining how to prepare formula more safely by mixing powdered infant formula with water which has first been boiled and then cooled to a temperature of no less than 70 °C before further cooling to feed the infant. This is the lethal or decontamination step which is required to inactivate any harmful bacteria. WHO guidelines explain: “Powdered infant formula, PIF, has been associated with serious illness and death in infants due to infections with *E. sakazakii* and *Salmonella enterica*. This is because, using current manufacturing technology, it is not feasible to produce sterile PIF. During the preparation of PIF, inappropriate handling practices can exacerbate the problem” (WHO 2007).

Often companies elaborate their own ethical codes of practice, usually voluntary, which spell out the company’s duties, rather than the consequences and impact of their products. There are no public sanctions for infringement against the company, only private sanctions against workers and management: <http://investopedia.com/terms/c/code-of-ethics.asp>. The shared responsibility for infant feeding requires more than a voluntary code of ethics; it requires international standards and enforceable national legislation. To address the problem of the aggressive and unethical promotion of commercial breast milk substitutes, WHO/UNICEF hosted an international meeting in 1979 on infant and young child feeding which called for the development of an international code to regulate the promotion and marketing of baby foods. Representatives of governments, technical experts, nongovernmental organizations, the infant food industry, and scientists working in infant nutrition attended the meeting, which led to the International Code of Marketing of Breast-Milk Substitutes, adopted at the World Health Assembly in 1981 as a recommendation of the highest policy-setting body in the field of international health. The recommendations for industry, health workers, and governments apply to the promotion of bottles, teats, and all breast milk substitutes, not just infant formula. But the international code was a compromise at the global level and considered a minimum requirement (Shubber 2011).

The 14 subsequent WHA resolutions “have further clarified or extended certain provisions of the Code” (WHO 2006); they require that complementary food and drinks not be marketed in ways that undermine breastfeeding (WHA 49.15, 1996). Complementary foods should not be labeled, advertised, or commercially promoted as suitable for infants under 6 months of age (WHA 39.28, WHA 54.2, 2001) “All governments should adopt the Code into national legislation. Since 1981, 81 countries have enacted legislation implementing all or many of the provisions of the Code and subsequent relevant World Health Assembly resolutions” (UNICEF 2011). The baby food industry is obligated to comply with these regulations even when national legislation has not been implemented.

Efforts to limit the marketing and promotion of commercial breast milk substitutes provide an example of how public advocacy has actually changed policies with regard to the role of the food industry in policy making, pointing out, for example, the conflict of interest inherent in the food industries' participation in public-private partnerships to "solve" infant and young child hunger problems.

Summary

Infant feeding practices are important for the sake of child survival, growth, and development and also for their far-reaching effects on adult health, including chronic diseases. They are a collective responsibility for all members of global society. While maternal breastfeeding is the ideal and normal way to feed and nurture an infant, efforts continue to make commercial breast milk substitutes safer and to bring the conflict of interest of baby food companies to public attention. For example, exciting new research on biome mapping of gut bacteria and viruses is intimately connected to improving infant feeding. But who should fund such research? Industry-funded research is suspect, but should tax payers' money be used to research constituents for infant formula rather than to offer support services for breastfeeding mothers? A safer pollution-free environment for breastfeeding mothers benefits everyone. Monitoring regulations on food safety and minimizing conflicts of interest benefit everyone. Infant feeding should matter to us all.

Informed Food Choice

Christian Coff

Centre for Ethics and Law, Copenhagen,
Denmark

Introduction

An informed food choice is an informed choice made about food consumption. It is a choice that is not made blindly. It is an enlightened choice made by the individual based on information, which has been obtained by the consumer.

When consumers make choices about buying something or not, or choose between different foodstuffs, information is believed to give clarity to the options. The aim of disclosing information is to increase the transparency of the food market, which is believed to enable consumers to judge, compare, and choose foodstuffs according to the values and preferences they find relevant.

Informed food choice is an ethical concept based mainly on two ethical principles: autonomy and integrity. The idea of autonomy emphasizes the consumers' rights to noninterference and self-governance. Informed food choice is a concept that relates to and to some extent is based on the ideas of informed consent and voluntary consent to be found within medical ethics. Common to all these concepts is the principle of autonomy as a basic value to be respected. In an ideal world, informed food choices are believed to be autonomous and voluntary decisions that are neither

manipulated by others nor coerced. Informed choices are, in opposition to coerced actions, based on liberty and freedom.

However, as food choices and consumption are closely entangled with social life, culture, and identity, food choices are not only about self-governance. Indeed, freedom to choose cannot be seen as an unconditional ideal when it comes to food choices. The principle of integrity refers to the life coherence of the consumer of which food culture and consumption is often a central part. Food choices are associated with caring for relatives, friends, and others and as such not independent but relational. The idea of integrity gives priority to the social, cultural, religious, and environmental contexts in which food choices are made and on which they depend.

It is common to analyze compound notions by breaking them down to basic components. This entry follows that tradition by analyzing the concept of informed food choice by examining the meanings of *choice* and *informed* in the light of the principles of autonomy and integrity.

Food Choice and Autonomy

The emergence of a massive consumer culture in affluent societies and a strong emphasis on individuality has contributed to a focus on *individual choices* (see, for instance, Taylor 1991, pp. 37–38). This development is reflected in the number of theories on choice: rational choice theory, public choice theory, social choice theory, and economic models of consumer choice. Food choice has also been theorized (see, for instance, Hausman 2012), often with the aim to map determinants in food choices. The accent on choice in theory and also in liberal rhetoric is not only a sign of a stronger emphasis on the freedom and rights of individuals. It is also a “mise en discours” or verbalization of the duties and responsibilities of the individual: the individual and consumer rather than society and the government are through the rhetoric of free choice and informed choice made responsible for that food choices are sound, healthy, sustainable, etc.

Central to the idea of informed choice is the concept of individual freedom, which is based on the normative idea of individual autonomy. Autonomy (Greek: *auto-nomos*) literally means self-rule, self-determination, or self-government, and in this sense it was originally used normatively in the description of sovereign (autonomous) nations. With the German philosopher Immanuel Kant, the concept was given a strong twist toward the individual. The idea of individual autonomy is normative in the sense that it is not something naturally given; it is a description of a vision of ideal decision-making. Autonomy is not something inherent in man; it is rather something to strive for and which is facilitated through education and cultivation (German: *Bildung*). As is the case with autonomy, we can also say that informed food choice is not something inherent or given; it is rather something to strive for and which must be facilitated through education in food literacy.

As part of the vision of the good life, the normative concept of autonomy is based on the negative experience of personal infringement or injustice when being forced or determined by external conditions against one's own will. Individual autonomy, as one of the oldest and most fundamental principles of civil rights, is intended to protect against infringements; it is the right of the individual to make decisions without coercion. Therefore, at a very general level, an autonomous choice is a voluntary action, which is not being forced upon one by external conditions. Hence, independence is traditionally considered a core value of autonomy. Autonomy then becomes the capacity for independent decisions, choices, and actions, which implies independence from others or from others' views or preferences (O'Neill 2002). This is often referred to as negative freedom or liberty: the freedom from interference by others. Therefore, choosing and free choice have traditionally been hailed by liberal thinkers, emphasizing the value of noninterference.

Based on the idea of autonomy, informed food choice entails protective arguments and productive arguments. Protective arguments are concerned with the protection of consumers from

fraud, deception, manipulation, and health risks. Productive arguments may, for instance, be concerned with specific qualities of food or production practices, like organic or free-range products, which are made known to consumers (see Rippe 2000 on protective and productive arguments as well as negative and positive liberties within food consumption). In both cases, communication and the disclosure of information to consumers are the keys to enable selection of products in accordance with specific consumer demands and thus to ensure some level of consumer autonomy. Hence, the autonomy of consumers should be understood not only as a substantive right, that is, as the right to simple non-coerced free choice, but also as a procedural right for consumers with regard to access to impartial and reliable information on food and the production of food.

The autonomy of food choices can be situated between the following poles: (1) voluntary/independent actions and (2) coerced actions. These poles are extremes and are also rare positions. Food choices are usually situated somewhere in between. Choosing food is a complex act as many factors influence food choices. Attempts to map determinants of food consumption choices are numerous and so are attempts to influence food choices. Marketing techniques are used to increase sales by specific product placements in shops and supermarkets, by the use of attractive packaging, advertisements, promotion campaigns, sales, and so forth. Healthy diets can be promoted by campaigns, nudging, taxation, prohibition, or by other means. Choices are often analyzed from three perspectives: persuasion, manipulation, and coercion.

A person can be *persuaded* or convinced by arguments to buy or eat certain kinds of food. This implies that choice is based on some level of independent and voluntary reflection. It also implies that some information is shared and may be even negotiated.

A person can be *manipulated* through, say, advertisements to buy and eat certain kinds of food, which implies that information given on the food is partial and may be incorrect.

A person can also be *forced* to eat certain kinds of foods. It is not uncommon that children dislike

some kinds of foods. However, parents may ask and sometimes force them to eat it anyway. Another kind of coerced food choice can be found in some institutions, like prisons or even hospitals, where people have no choice than to eat what is served. Poor people may likewise have no other opportunity than to buy the cheapest available food.

Information and Integrity

Basically, food choices occur in two main settings: (1) shopping for food (or when growing food for oneself) and (2) eating and drinking. In both settings food choices might be made by oneself and for oneself. However, food consumption is rarely a completely solitary activity but in fact a social activity. As much as food is shared in communal eating during meals, much food shopping is not only shopping for oneself but also shopping for others. The relational aspect of food shopping comes about when, among other factors, other peoples' food preferences are taken into account (Coff 2013). Food shopping choices are thus not made in a vacuum but in social settings, where others' views and preferences are taken into consideration.

Likewise, participants in social meals care for social relations and other peoples' reactions. It is common that food manners require that food served by the host is not rejected – even in situations where the guest may not find the food tasty or edible – as this might be seen as a sign of lack of appreciation and community feeling. This relational aspect of food consumption often emphasized by food sociologists indicates the limits of the idea of autonomy and the need to supplement it with other ethical notions. The concept of integrity can be used to normatively describe the relational aspects of food consumption. Integrity can be both a virtue describing the honesty and reliability of a person as well as describing life coherences of a person, which should not be manipulated or destroyed (Rendtorff and Kemp 2000, p. 39). The life coherence of a person is the life story of that person and the relations that person has. Because food choices and

consumption do have consequences for others and the environment, food choices and consumption can be seen as expressions of relations to other people as well as to the environment (see Coff 2006 for a detailed description of the relational dimensions of food consumption).

The idea of informed food choice is that food consumers should be informed about food in order to respect consumers' integrity and autonomy and thus to enable consumers' consent. Beauchamp (2010, p. 56) states that in general the literature on informed consent proposes five elements as the analytical components of informed consent: competence, disclosure, understanding, voluntariness, and consent. This approach can be used in the analysis of what informed food choices entail on the informational level by asking the following questions:

- What are the competences needed by food consumers?
- What information should be disclosed about food?
- How should consumers be informed about food in order to enhance their understanding?
- What makes an informed food choice voluntary?
- What do food consumers want to consent to?

To begin with the questions on what information to disclose and what food consumers want to consent to, it is important to note that the idea of informed food choice concerns a specific kind of information, namely, information about the food product itself – and usually not on the food preferences of someone else that one is shopping for. This is important as it shows something about the nature of the information to be disclosed. Mapping of consumers' concerns about food shows what kind of information food consumers find relevant as issues, i.e., the issues that consumers want to be informed about, respond to, and eventually consent to. Table 1 shows a list of major consumer concerns about food. These concerns can be considered as major issues driving the demand for informed food choice. The first seven concerns can be described as substantial and the last three concerns can be classified as

Informed Food Choice, Table 1 Ten consumer concerns about food production (Coff et al. 2008, p. 11)

1. Animal welfare
2. Human health
3. Methods of production and processing and their impact (e.g., environmental, landscape)
4. Terms of trade (fair price, fair working conditions, fair salaries, etc.)
5. Working conditions
6. Quality (intrinsic qualities such as taste, composition, etc.)
7. Origin and place
8. Trust
9. Voice (participation)
10. Transparency

procedural as they refer to how information is shared and decisions are made.

The list shows the embracing character of food consumption (see also entry on Food Policy and Ethics for the embracing character of food policy). Consumers may ask for or demand informed food choice to assist them in decision-making in relation to a number of issues: avoiding or reducing health-related risks; comparing products for culinary qualities; estimating ethical aspects of a foodstuff like environmental impact, working conditions, or animal welfare; or simply to enhance trust in the food consumed. The list of consumer concerns given here is not complete, and it is most important to understand that consumer concerns are dynamic and vary among people. This means that the issues to be informed about are indeed not static but are under constant development.

Choosing food can be a highly reflective activity, based on careful judgments and evaluated arguments, which take several consequences of food consumption into consideration. Many of the issues mentioned in Table 1 are captured in the concepts of political and ethical consumption. Political and ethical consumption is a reconfiguration of the consumer’s role, merging it with the citizen’s role, which has lead to the term citizen-consumer (Korthals 2004, p. 149). Surely, few consumers are seriously concerned about all the issues mentioned in Table 1. It is more common to be concerned about a few of the issues

mentioned and take action on these or to be only superficially concerned and not take any action on it.

The issues mentioned in Table 1 can be considered as what consumers might want to consent to in relation to food. If, for instance, novel foods and other new food processing practices pose new risks to health, consumers may want to be informed about it in order to consent to it or not. The comparison of informed food choice with informed consent used in medical ethics seems especially appropriate when it comes to the consequences of food intake on health. Frewer et al. (2002) confirms that in general people want to be provided with information on food risks in an understandable and intelligent way in order for them to make informed choices about exposure to food risks.

In view of the ten concerns listed in Table 1 and given the fact that food choice is embedded in cultural, social, biological, ethical, religious, and commercial contexts, it is obvious that informed food choice can be a demanding process. Judgment of food qualities in relation to the ten concerns requires a high level of competence among food consumers. However, consumer competences vary a lot, and their ability to understand information on food can be limited by, for instance, immaturity, irrationality, or lack of interest. Food policies improving food literacy have been proposed and adopted in several countries in order to enhance consumer competencies. However, the idea of informed food choice in itself should also help competent and interested consumers to enhance their level of understanding and improve the process of decision-making.

The question on how to inform consumers is intriguing and challenging. The amount of information that can be communicated about foodstuffs is potentially enormous. Scientific uncertainty when it comes to, for instance, health claims and the environmental impact of different kinds of food production practices like organic farming and conventional farming contribute further to the opacity of information about food. The effort needed by consumers seems intimidating and immense in the light of the endless number of food products and the complex consequences that food production and food consumption have on health,

environment, fair trade, etc. Furthermore, poor communication between producers and brokers in the food sector makes it even harder for consumers to find wanted information on food.

Food labels have been introduced to reduce complexity and make choices easier for consumers. However, labels have also been accused for being too reductionist: Klompenhouwer and Van den Belt (2003, p. 548) argue that labels and claims (and also advertisements) about food health run the risk of being quite superficial and also that the actual wording of a claim can be interpreted in different ways.

At the other end of the spectrum, much more detailed information on food can be presented by the use of the Internet. Codes, like the QR codes, presented on the packaging can make information on food products easily accessible for consumers by the use of QR scanners in smartphones or computers (Beekman et al. 2008, p. 289). This approach can be characterized as user-friendly as it potentially allows consumers to search for specific information relevant to them, and thereby sorting out irrelevant information. On the other hand, this approach runs the risk of information overload, which is known to reduce consumer engagement.

If informed food choice is to be of any value, it is paramount that the information provided on the food is trustworthy. To ensure trustworthy information impartial third parties can be asked to control and guaranty that disclosed information is correct.

The voluntariness of consumers' informed food choice is ensured when no unwanted influence is exerted and when consumers are not controlled or manipulated by other persons or institutions. A kind of coerced consumer choice can occur when only one product or brand is available. In the case of market monopoly, consumers may be "forced" to buy a specific brand of, for instance, milk as the only alternative is not to buy any milk at all.

Critique of Informed Food Choice

Individual choice has been used in liberal and market-oriented rhetoric to describe in positive

terms the emancipation of the individual from social ties. In this context, the word choice embodies the freedom to choose one's own individual lifestyle. In affluent, market-oriented societies, consumption choices are seen as a means for the realization of the self and for the creation of personal identity. There are, however, also critical positions deploring the development of the consumer society and the culture of choice.

Baudrillard (1998) describes what he calls a "phenomenology of consumption," pointing to the shallowness and fragility of consumption cultures. For Baudrillard consumption is characterized by self-interest and hence ignorance of the surrounding world. His phenomenology of consumption describes how attention and concern are turned toward individual consumption and satisfaction at the expense of care for other human beings and the common good.

Another critic of free choice is Schwartz (2004). According to him free choice is hailed in liberal cultures as the new dominant ideology: "[O]ur culture sanctifies freedom of choice so profoundly that the benefits of infinite options seem self-evident." However positive freedom of choice may seem, it has several ramifications on the more philosophical, existential, and psychological aspects of life. When it comes to food, the number of choice opportunities in supermarkets is enormous. As a consequence the time spent on shopping for food is increasing, as it is time-consuming to seek information and compare food products. Comparison of foodstuffs and considering alternatives may lead to other anxieties: for what if the choice made is not the best, but turns out to be the worst choice? This is referred to as the tyranny of comparison or the tyranny of small decisions, which instead of making consumers happy makes them worried and anxious. According to Schwartz (2004, p. 221) "having too many choices produces psychological distress, especially combined with regret, concern about status, adaption, social comparison, and perhaps most important, the desire to have the best of everything – to maximize."

Other critics of the informed choice rhetoric have argued that it is used as a liberal pretext to shift responsibility from the political system to

individualized consumers, thereby making peoples' individual lifestyle responsible for health, environmental sustainability, etc. An example of a health policy that emphasizes informed food choice and lifestyle can be found in the UK government's White Paper on public health (HM government 2004) in which it is argued that "people want to be able to make their own decisions about choices that impact on their health and to have credible and trustworthy information to help them do so."

Another critique stresses that not all issues are suited to individual choices. Some issues are too complex for consumers to take a stand on – such issues should therefore be regulated by public authorities. Food safety has been mentioned as being such a highly complex issue that should not be left to individual choice but rather regulated by public authorities. Scientific uncertainty, for instance, about the health effects of foodstuffs, has also been mentioned as a worry that makes individual choice by consumers inappropriate.

To carry out informed food choices is demanding in terms of knowledge, competences, and intellectual capacity. Informed food choice favors educated and enlightened people and especially those who are in possession of food literacy. Critics argue that less skilled people are unlikely to use disclosed information about food in their food choices.

Finally, the information overload of consumers is seen to be a general problem of informed food choice as consumers only have a limited amount of attention for food (Berg and Gornitzka 2011). Labeling as a strategy to reduce information to easily recognizable symbols like organic labels or animal friendliness is widely used in the food sector. However, as the number of informative labels increases, food labels may also add to the lack of transparency on the food market.

Conclusion

Food production and consumption influence health, environment, social structures, etc. For this reason consumers are increasingly interested in information about these effects. Disclosure of

information about the consequences of food production and consumption is essential for the idea of informed food choice. An informed food choice is an enlightened food choice made by the individual based on the information made available. Food choices are made when shopping for food or when eating/drinking, and information is believed to give clarity to the options by increasing market transparency, supporting rationality (the best choice), consumers' self-governance (autonomy), and life coherence (integrity). On a practical level, informed food choice remains an ideal to strive for, as information on food often is inadequate.

Synonyms

Factors of change in food and agriculture; New services and products in food and agriculture

Introduction

Innovation means change. In a case of food and agriculture, it can be the application of new proposals for raw material processing technology,

packaging of products, new food additives, and new agricultural technologies. Innovation may lead to reducing or preventing adverse changes caused by microorganisms, oxidation of food ingredients, and enzymatic and nonenzymatic reactions, as well as ensuring safety by inhibiting the development of some pathogenic microorganisms. Change can also provide healthier and more nutritious food. The food is tastier because of the prevention of adverse qualitative changes in food composition, including organoleptic changes, and changes in the perception and pleasures from eating food. In addition, crops can be more abundant thanks to reduced exposure to diseases, adapted agricultural treatments, or higher resistance to changing weather conditions.

The above are examples of innovation in food and agriculture. However, the literature about innovation in them is still insufficiently developed compared to studies on innovation in the high-technology sectors. A general definition of innovation says that it is the introduction of change to something new. Innovation may be things, ideas, or practices that are introduced to an audience, consumers, or users. In the “Oslo Manual” (OECD, Eurostat 2005), innovations are described as the implementation of a new or significantly improved product or process, an innovative marketing method, or a new organizational method in business practices. The meaning proposed in the “Oslo Manual” indicates changes that are first developed by an organization and those imitated by other organizations. All the above types of innovation can also be found in food and agriculture.

In general, innovations in the food sector are more incremental than in other sectors. This means that they often rely on slight changes in existing products, a product's components, or processes. Incremental innovations are related to the adaptation, refinement, and enhancement of existing products or processes. Radical innovations are understood as entirely new categories of products or processes and are less frequent in food and agriculture production than in other sectors. An example radical innovation in food is aspartame, a sweetener used in many products all over the world. These rare innovations in food

manufacturing are often unplanned, serendipitous results of creative processes.

For food producers and processors, innovations are seen as the primary determinants of organizational success because innovative solutions and products allow for high performance and survival of an organization on the market. From the farmer's and manufacturer's points of view, they are also essential to increase consumer attractiveness and availability of food products. Other goals include increasing production efficiency by reducing losses and improving agri-food production efficiency.

Role of the Technology Push Model for Innovation in Food and Agriculture

The food and agriculture sector is characterized by a low level of technology, and this is how it is classified (Hirsch-Kreinsen and Jacobson 2008). However, it can be stated that innovative changes in the described industry can be related to the technology push model: innovation originates from innovative technologies. There are several arguments for finding that innovations in the sector are in line with this model.

First, the products offered by the sector are very diverse, as are the producers and processors themselves. The products that agri-food sector produce can be considered, among others, from the point of view of the raw materials that are used for production (e.g., meat, fish, and fruits), product functions (e.g., functional food or nutraceuticals), the level of novelty of products (e.g., novel food and traditional food), or the used methods of production (e.g., organic or genetically modified). Furthermore, some producers use innovative methods of production based on scientific research (e.g., functional foods). There are also enterprises in the sector using traditional production methods, which cannot even be changed in any way if the producer wants to get the appropriate labeling of products delivered to the market (e.g., protected geographical indication in the European Union).

Consequently, entities operating in the agri-food sector can be divided into two groups due

to the method of technology transfer necessary to manufacture innovative products. According to the scale presented by K. Pavitt (1984), there are (1) companies with the absolute scale of production and (2) those belonging to entities dominated by suppliers of technology. In the first case, the source of innovation is an organized structure of task division in which research and development (R&D) departments are often created. The same entities design, build, and manage production systems. Therefore, the products of such organizations are often very innovative, and innovations have a radical character. The second group is represented by entities that absorb technologies embodied in acquired machines and devices. Technology transfer from abroad is carried out using the mechanism of importing capital goods. The benefits of the transfer consist of increasing professional skills related to gaining access to new knowledge. Therefore, these entities do not create their innovative advantages but instead focus on the acquisition of such advantages from their suppliers. Thus, changes in technology offered by suppliers also affect technological changes in the agri-food sector. Here we deal with incremental innovations in food and agriculture.

Another phenomenon of the agri-food sector related to the technology push innovation model is industrial convergence. This means that we can observe the application of various technologies across different industries, and this process can result in new "interindustry segments" (Bröring 2005). Industrial convergence can be defined as the blurring of technological and regulatory boundaries between different separate industries. Convergence offers many opportunities for new business areas, but companies must use knowledge and technologies that are not covered by their traditional knowledge. Technological progress in various fields of science creates many possibilities of increasing the added value of food products that meet the requirements of consumers. Convergence of the agri-food sector can occur with, among others, pharmaceutical, chemical, biotechnology, nanotechnology, packaging production as well as with the sector of the machine and device manufacturers (Bröring 2005). Recently, the trend of using information

and communications technologies (ICTs) in the agri-food sector is also prevalent. This process is evident in technical systems that use drones, sensors, and big data analytics. There are also solutions ranging from simply ordering food applications in the Internet to, for example, services based on the Internet of Things or the block chain technology.

Role of Biotechnology in Food and Agriculture Innovation

Concerning agri-food industry, convergence can also be seen in the use of biotechnology and genetic engineering. There are opportunities for it that can provide the high technological and productive progress, provided farms and processors to such technologies (Sarkar et al. 2018; Caira and Ferranti 2016). Biotechnology has contributed to the application of solutions associated with the production-intensifying path of innovation. As a result, it is possible to use selected seeds, mechanization and agrochemical fertilizers, herbicides, and pesticides. It leads farmers toward specialization and monocultures in crops and breeding. Another use of environmental biotechnology is in organic agriculture to solve environmental problems, e.g., soil fertility, technogenic soil pollution, and soil salinization. The goal is to neutralize the effects of adverse human impact on the ecosystems and to popularize the idea of “feeding the soil rather than plants.” Innovations may concern, among others, biological treatment of wastewater, recycling of organic wastes, biological deodorization of gases, purification of contaminated soils (bioremediation of soils), silt, settled sludge, reservoirs, restoration of soil fertility, surface-active substances, and preventing corrosion, zero tillage, as well as biological nitrogen fixation and reduction in the need for chemical fertilizers that can be achieved by cultivating legumes (Materia et al. 2015; Ociepa-Kubicka and Pachura 2017).

There are also biotechnology innovations in food additives that can be obtained by fermentation, tissue cultures, or using enzymes. Genetic engineering makes it possible to create additives, even whole products (e.g., hamburger or milk

from the laboratory), which are used in food production. The products of “cellular agriculture” are chemically identical to the natural products from, for example, meat and milk. Manufacturers claimed that they have the same taste and texture.

The technology is attractive for many reasons. It could reduce the world’s reliance on livestock, decrease greenhouse gas emissions, and lessen the use of traditional farming. Also, it appears that such production is more attractive from the point of view of food safety because existing livestock practices are related to antibiotic resistance, viral outbreaks, and bacterial food contamination. Moreover, products may be addressed to particular markets, such as meat with less saturated fats, milk without lactose, or eggs without cholesterol, which may be particularly necessary due to the increase in the population of people with different food allergies or obesity. It seems, however, that despite the consumer resistance, many genetically modified products may be particularly attractive, if not for everyone, at least for specific groups of consumers. For example, genetic modifications may eliminate gluten from wheat grain and lower the cholesterol in meat.

Another direction of innovation development in the food sector is the opportunity to customize both foods according to individual’s genetic makeup or nutrigenomics. Nutrigenomics as a combination of nutritional science and genomics is a new area with high innovation potential. Scientific knowledge in the field of genomics, plant cultivation, genetic engineering, and modern medicine is combined with the goal to develop individualized nutritional products for medical prophylaxis and treatment that reduce the distance between food and pharmacy. It is a consequence of the convergence of industry between the pharmaceutical and food industries leading to products such as lowering cholesterol by consuming margarine with the specific ingredients. Convergence has led to the emergence of a new sector of nutraceuticals and functional foods (Martinez 2013). Such products are not only the result of the development of innovative technologies but also the effect of the growing trend for health and well-being, which is continuously growing the

sale of hybrid products, such as products lowering cholesterol.

Role of the Market Pull Model for Innovation in Food and Agriculture

The second type of driver for innovation in food and agriculture is market needs, also known as market pull. The development of new products is necessary to adopt changes to the needs of consumers (Grunert et al. 2011).

The primary determinant of innovation in food and agriculture is the resistance of consumer. This concept explains consumer response to innovative products and processes, especially their reaction to radical innovations. Usually, it occurs in the initial stages of new product or technology adoption life cycles. D.I. Padberg and R.E. Westgren (1979), however, while examining the nature of innovation in the food industry, presented the concept of consumer inertia. They hypothesized that consumers reveal a specific risk aversion regarding the choice of new food products because although they expect new products, they are counting on the fact that new products will be similar to the already known products. This means that consumers prefer changes that are incremental. This, in turn, influences patterns of consumption and the type of product innovations introduced, which often do not go hand in hand with the possibilities of technologies available on the market. Therefore, D.I. Padberg and R.E. Westgren (1979) define the concept of “redundant technology,” according to which technology and food science offer numerous possibilities of changing the characteristics of a food product (e.g., taste, nutritional content, or preparation method). However, food businesses do not take full advantage of these possibilities because there are specific demand conditions on the market.

There are some consumer psychological characteristics that affect the “willingness” to innovate. There are personality traits, attitudes, previous innovative experience, perception, motivation, and beliefs. However, also very important is if the consumer may not have the ability to

innovate. These characteristics are demographic variables, namely, education, income, mobility, and age. For example, a consumer whose current lifestyle is associated with some food brand (e.g., Coca-Cola) is unlikely to purchase its substitutes. According to Ram (1987), compatibility denotes consistency with the consumer, traditional, and cultural values and with consumer lifestyles. Moreover, there are consumer-perceived risks that innovation can bring, such as a physical risk that can cause harm to a person, functional risk related to the situation in which innovation does not function properly, psychological risk as a result of the fear of being seen undesirably, and economic risk concerning the situation with better or cheaper version. All these determinants of consumer attitudes to innovation in food and agriculture constitute significant barriers to innovation.

In response to the above restrictions, it is essential for food producers and processors to take a consumer-driven approach. It means that the determinant of the company's and farm's activities is to meet the needs and expectations of the consumer. Regardless of eating habits and the phenomenon of consumer inertia, in developed countries, there is a definite trend in “consumers' willingness” to pay for new and improved food products. The occurrence of consumer inertia does not mean static patterns of food consumption, as they change, but this is quite slow. In fact, there are numerous factors (e.g., higher income, demographic changes, market trends, or increased access to information), which determine continuous slight changes in food consumption and lead to consumer interest in new food products.

One of the factors that radically changed consumers' behavior in the food market and influenced the ability of the consumer to innovation is disposable income. Higher disposable income means that consumer position on the market strengthened. It causes a short life cycle of products and even constant need to introduce innovation in food and agriculture. In addition, the consumer is looking for convenient products such as pre-peeled, washed, or cooked vegetables; frozen, semi-cooked products; and dinner dishes

to be heated. These innovations are also the result of the increased participation of women in the workforce, so households encounter time constraints related to the preparation of meals and, consequently, perceive convenience as an essential feature of food products. Hence there is a growing willingness to pay for services included in food products. At the same time, the role of product diversity is being increased. This is the result of an increasing emphasis on quality in general, higher concern for nutritional and health properties, and food safety.

Consumers are also interested in new combinations of flavors, aromas, and product forms. The above expectations translate into new products and processes. Consumers expect products that are low fat, low calorie, no caffeine, unsweetened, low in sodium, or low in cholesterol. Therefore, there is market potential for new food products that have better nutritional and health properties but retain the same functional and sensory features as traditional products. For many consumers, eating food is a sensory experience. Especially in developed economies, food is no longer considered merely as a means of satisfying physiological needs. It should instead be treated as a product of the “experience economy” that can be enjoyed through its taste, appearance, and sometimes also aroma in specially designed environments.

Because of changes in consumer needs, there is a significant flow of new or modified food products on the market. In recent years there has been an ever-increasing product proliferation that has new features, which is the result of the previously indicated issue of consumer inertia. As a result, companies minimize market risk by selling new products that are only slightly different compared to products already on the market.

On the other hand, as T. Levitt (1975) pointed out, competition on the market will increasingly concern not competing companies with what will be produced in them but rather through what will be added to such a product in the form of, for example, packaging, services, consumer advice, delivery terms, and other issues that will give added value to the consumer. For example, a favorite functional food can be given as an

example of products that are often of a conventional nature, which have been added additional value. The augmented product adds value to the core product, usually exceeding customer expectations (Kotler and Keller 2013). Product differentiation often arises on the basis of product augmentation. Product differentiation, especially in the augmented level of a product, has been used extensively as a tool to capture consumers’ interest. When conventional food products are becoming more diversified, some of them by incorporating sustainable product characteristics, organic food products receive a “push” to become more diversified as well. For example, further development of the organic food market and increased consumer loyalty could be achieved by adding “extra ethical” attributes to organic products and thereby enhancing their value to (some) consumers (Zander et al. 2013).

The change of consumer needs in the food market has influenced its structure and, also, resulted in the dynamic development of services related to distribution and retail trade. In this context, food safety, related to the supply chain, is of vital importance to consumers. The traditional, long food supply chain leads to a situation where it is difficult to guarantee food safety. For example, there are numerous cases of fraud in the food industry that have destroyed consumer confidence in the food supply chain, affecting the agri-food sector. Unfortunately, these scandals have significantly contributed to the destruction of the overall image of the agri-food sector in Europe. The outsourcing in the food sector leads to the extension of the supply chain and brings with it the problem of trust between clients and contractors. This, in consequence, leads to a reduction of confidence in the food producer from the consumer. Short food supply chains are some innovation. This requires the strengthening of local food chains, with substantial involvement of both producers and consumers. In this way, producers can regain an active role in creating the value of such a chain and the product itself. Such a solution allows producers to shorten the path that food must go to the consumer (Ilbery and Maye 2005). Together with the growing requirements of consumers, but also those on the part of

lawmakers, the traceability of the origin of products has become increasingly important. It means tracking and tracing the flow of products down and up the supply chain. These reasons for innovating may stem from the lifestyle of different consumer groups, for example, the Millennials generation that show higher demand for organic products, sold ethically and for healthy food. They become, therefore, more conscious clients. They are supported by the possibility of using mobile devices to analyze information about products or their purchases from specific, satisfying sources.

Conclusion

The innovation in food and agriculture may be simultaneously technology-driven and market-driven. Consumers have increasing expectations for food that will be part of a healthy lifestyle. They expect products from food companies that meet their nutritional needs, which may require the producer to change product formulas or the way products are delivered. To be able to make informed choices, they also expect precise information about the nutritional value of the products and the source of their origin. For the consumer, the quality of the raw material used for production, the applied processing, storage, and distribution technologies are becoming increasingly critical. Consequently, the changes that manufacturers make should be responsible innovations. The response from food companies may be, for example, food certification and supply chains that can allow better supervision of the flow of agricultural products and raw materials “from farm to fork” and consequently allow building consumer confidence.

Governments and new regulations that abandon or allow specific production factors for innovations (e.g., new ingredients) are also some drivers for innovation in food and agriculture. They promote practices that must be responsible – especially if there are food additives in which case the processor or producer of food complies with the standards for the level of additives used. However, thanks to the law regulations, corporations have been legislated or pressured to

minimize or eliminate ingredients known to be harmful, but they must feel responsible for their production.

Institutional Food Service

David S. Conner
University of Vermont, Burlington, VT, USA

Introduction

Institutional food service can be defined as entities that provide meals at institutions including schools, colleges and universities, and hospitals, as well as correctional facilities, public and private cafeterias, nursing homes, and day-care and senior centers. Interest lies in their potential roles in sourcing food from regional farmers, ranchers, and processors, thereby contributing to the development of regional food systems through farm to institution (FTI) or farm to cafeteria programs, of which farm to school (FTS) is the best known case. These programs combine local food procurement and

experiential education to forge closer ties between farmers and consumers.

These programs are large in number. As of March 2013, the National Farm to School Network estimated there were more than 12,000 FTS programs, existing in all 50 states and reaching 5.7 million schoolchildren. Programs and organizations such as the National Farm to School Network, Real Food Challenge, and Health Care Without Harm support these efforts in other types of institutions nationwide. The School Food FOCUS project has collaborated with large US-based K-12 schools to address procurement issues unique to schools with 40,000 or more students.

Institutions provide a potentially large market outlet for US farmers: the USDA Economic Research Service estimates that \$36.5 billion was spent on food at schools and colleges in 2010, equaling 6% of all away from home food purchases. In comparison, the 2007 Census of Agriculture reports \$1.2 billion in annual sales of food direct from farmers to consumers in the USA. Furthermore, combined with the experiential education, farm to institution programs can potentially encourage healthy eating habits, increase access to healthy foods, create loyal customers, and support rural communities (Bagdonis et al. 2009; Vallianatos et al. 2004).

There are several other reasons why scholars and practitioners are interested in institutional food service and FTI as a food system development strategy. First, they purchase food in fairly large and predictable quantities, unlike high-end restaurants or retailers, for example, whose demand fluctuates with economic cycles to a greater degree. Many institutions have educational missions, using food service operations to enhance food, agriculture, and nutrition lessons. Finally, on the whole, individual institutions, particularly schools, are not direct competitors; unlike supermarket retailers or restaurants, sharing information or best practices with another institution does not risk customers leaving to eat in another location. The plethora of support organizations and their willingness to share information is further evidence of this.

K-12 schools are a large and important sector of institutional food service. K-12 school meals are governed by the USDA National School Lunch Program. This program, founded in 1946, provides money and food to participating schools. Funding for these programs comes from periodic reauthorizations of the Child Nutrition Act. As of the 2012–2013 school year, schools receive up to \$2.86 per meal served (USDA Food and Nutrition Service 2009). Despite the best efforts of this program, two principal intended outcomes, farm profitability and childhood health, remain elusive. According to the 2007 Census of Agriculture, the majority of US farms earned negative net income. Childhood obesity remains a persistent problem.

There are, generally speaking, three models by which food service operations can procure food. First, in the farm-direct model, institutional buyers purchase directly from farmers: farmers to deliver to schools or schools pick up from farms. Second, they can buy from one or more types of intermediary, such as a distributor specializing in locally grown foods or food hub. Third, buyers can purchase from a broadline distributor, who delivers fresh and processed (e.g., canned, frozen) food items as well as nonfood supplies such as paper products. For institutional buyers, the farm-direct model offers the closest connection farmers, the most information about how the food was produced, and the greatest opportunity for experiential education. Farmers receive 100% of the food dollar.

As discussed below, high transaction costs of this model limit the quantity of product procured farm direct. At the other end of the spectrum, broadline purchases offer buyers the least connection to farmers and opportunity for experiential education. Farmers only receive a percentage of the food dollar, as distributors charge for their services. Given its efficiency, reliability, and low transaction costs, this model is well suited for routine high-volume purchases. A primary challenge of institutional food service in general and school lunch in particular is to supply healthy foods that provide connections to and support local farms in an affordable way. This task imposes a number of trade-offs, as discussed below.

Transaction Costs and School Food

Institutional food service procurement strategies are explained by transaction cost theory in supply chain analysis. Transaction costs are those needed to seek out and negotiate prices and ensure quality of a good or service. Transaction cost theory is based in large part on Coase's seminal paper (Coase 1937) and has been applied to many industries including manufacturing and food distribution. Following Coase (1937), a firm faces the choice of procuring inputs in-house (make) or acquiring inputs by contract or on spot markets (buy). The higher the transaction costs, Coase argues, the more likely the firm will make rather than buy. Subsequent studies have framed the issue as a continuum of models for procurement (Dyer 2000; Hobbs 1996). At one end of a continuum is vertical integration or hierarchy, where a firm produces its needed inputs in-house or otherwise exerts a great deal of control over the process. At the other end of the continuum is the use of arm's-length spot markets, where the firm shops for the best price each time it purchases inputs. In the middle of this continuum are many possible means of coordination, including partnerships, where the firm buys from a limited number of preferred suppliers often creating long-term strategic relationships with them.

The literature on transaction costs and economics suggests circumstances when each model will prevail (Dyer 2000; Hobbs 1996; Kumar 1996). The vertical-hierarchy model – the “make” option – is used when inputs are highly differentiated or of high quality: control over inputs is needed to ensure quality. Spot markets or contracts – the “buy” option – are used for frequent and highly routinized transactions of homogeneous or low-quality inputs. The same input is available many places, so the buyer can afford to simply choose the one with lowest cost. Strategic partnerships occupy a middle ground in this continuum. Partnerships are best used when vertical-hierarchy arrangements are too slow to adapt and innovate, but arm's-length suppliers are not willing to invest in equipment or share information needed to achieve needed innovation (Dyer 2000; Kumar 1996).

In practice, institutions utilize procurement and preparation options on various points of this continuum, many residing along the “buy” side. For example, K-12 schools are required to utilize an open bidding process for many food items, which may take a number of forms. Closest to the “buy” end of the spectrum is competitive sealed bidding, which entails creating specifications for desired products and then publically inviting sealed bids and choosing the bidder able to provide needed products at the lowest price. This option is best when specifications are complete and easily communicated and when price will be the only dimension of variation, and it is believed many potential firms are willing and able to provide the items. In this case, transaction costs are embodied in the specification and request for bids, with price being the only decision factor.

In the middle of the continuum, competitive proposals can be solicited to achieve objectives (more loosely defined than specifications), and institutions choose a vendor who best meets objectives, with price being an important but not the sole criterion. Finally, institutions can negotiate with prospective vendors to meet objectives, which may be achieved in several possible ways. These options add complexity and transaction costs to the process and require some element of partnership but are still largely arm’s length and use a formalized and regulated mechanism: the institutions exert little control over production or distribution once basic terms are set.

K-12 schools are able to procure limited amounts (\$100,000 is the federal threshold, although states may require lower ones) of fresh, unprocessed locally grown produce under the geographical preference provision: this exception to formal procurement practices is critical for FTS programs. Institutions are able (but not required), at their discretion, to contact vendors directly to solicit bids and arrange for delivery rather than publicly advertise and accept bids from anyone. Clearly, this approach may require greater transaction costs in order to procure more specialized and differentiated products – locally grown and often with the farmers’ name and story attached, for example.

Finally, an institution may choose, on a limited basis, to produce food itself, such as in a school garden or school farm. In this case, the product is very specialized – grown by the students themselves – and requires a great deal of control on the part of the schools, in the form of specialized training protocols and employee oversight. The value of school garden or school farm food is generally educational rather than being efficient method for school food procurement.

Institutions also have a number of options regarding preparation of food. Institutions can take a more vertically integrated approach, utilizing scratch cooking in either institutional kitchens or central commissaries: this option has high costs of organizing production (labor, equipment, management) but permits a great deal of control over product ingredients, for both nutritional and educational purposes. Scratch cooking can produce high-quality and highly specialized meals. In contrast, institutions can serve highly processed, heat-and-serve meals in which the costs of organization are borne by manufacturers; in this case, the institution has little control over ingredients.

Institutions even face the “make or buy” trade-off in the overall decision of who will operate the institutional food service. A school district, for example, may choose to be “self-operated,” in which the district organizes all activities using its own capital, management, and labor: those preparing and serving the meals are public school district employees. On the other hand, many institutions choose to “buy” their food service outright from a contractor, inviting bids from food service management companies and choosing largely on price and then having the contractor organize all procurement and production activities.

Institutions other than K-12 schools face similar trade-offs in transaction costs and the make or buy decision. On the most basic level, they may be self-operated (make) or use a food contractor (buy). Michigan State University is self-operated, for example, while the University of Vermont uses a contractor. Institutions that receive no public money face less stringent requirements to use competitive bidding for procurement decisions and therefore have more flexibility. These institutions are able to incur higher transaction costs and

serve more locally grown or other specialty foods if they are able to pass the costs along to their customers.

Motivations and Perceived Barriers of Supply Chain Actors

Previous studies have identified a diverse set of actor motivations and perceived barriers in farm to institution markets. Farmer motivations to participate include a mix of economic factors like the ability to diversify markets with those which offer reliable, consistent volume and the ability to sell #2 grade product, as well as social factors like the desire to feed children healthful food and contribute to their communities (Conner et al. 2011, 2012; Izumi et al. 2010b). Distributors cite their relationships and willingness to work with local farmers as conferring an advantage in the face of growing demand for locally grown food (Izumi et al. 2009). Food service buyers cite a number of benefits such as improved food quality (and concomitant increases in meals sold/served), support for local farmers, and greater buy-in from school employees and community members (Izumi et al. 2010a; Vogt and Kaiser 2008; Feenstra et al. 2011). Relatively low volumes (compared to sales to major retailers or brokers), arduous paperwork, and low prices are commonly expressed barriers to farmers. Distributors and buyers mention a suite of barriers around logistics, reliability, availability, and consistency (Vogt and Kaiser 2008).

Lessons Learned and Keys to Success

First, a common theme in lessons learned is the need for a champion, someone within the institutional food service operation to begin and sustain FTI efforts. Key roles of champions include linking stakeholders, providing energy and momentum, and providing a go-to person to navigate logistical issues. Practitioners can help to foster FTI through efforts to discover, recruit, mentor, publicize, and otherwise support champions.

Second, relationships among supply chain actors are critical to create transparency and trust and to allow for creative problem solving of logistical issues. These relationships are often built on shared values such as concern for childhood nutrition, community economic development, farmer well-being, and food system education. Third, economic self-interest matters. Social motives alone are not usually sufficient to encourage farmer participation; concomitant economic benefit is needed. Many supply chain actors express instrumental value in their ability to source and serve locally grown foods as providing a differentiation strategy for their businesses. Schools with FTI programs cite both increased participation rates (the percentage of students eating school meals) and increased community support. Finally, support organizations, particularly those able to assist with procurement (helping food service buyers find locally grown foods) and educational activities (developing and sharing materials to link food with local farmers), are critical to FTI success. Education linking the farmer to the food has promise to improve dietary habits (Izumi et al. 2010a; Roche et al. 2012).

Lingering Barriers

Several factors will likely continue to inhibit FTI growth. Institutions, especially K-12 schools, face severe budget constraints; to the extent that local foods cost more, institutions' ability to buy more than token amounts will be limited. Certain institutions, especially colleges, universities, and some hospitals, may be less cost constrained. Second, in many areas, seasonality limits the times in which fresh produce is available; indeed, for many (e.g., schools, colleges, and universities in the USA), the period in which produce is most available is the time in which the fewest students are attending classes. Season extension technologies (flash freezing, high tunnels) can help address this. The final barrier is the financial status of support organizations. Many of these are grant-funded; while FTI efforts are in the spotlight and receiving support now, these organizations must

seek long-term funding to continue operations when grant funds dry up.

Summary

Institutional food service is comprised of entities that serve food at schools, hospitals, and other institutions. Interest in these programs lies in their ability to contribute to food system development goals, particularly childhood nutrition and farm viability. This entry discusses the difficult options institutions face in procuring locally grown foods within a transaction cost theory framework and then highlights supply chain actors' motivations and obstacles. It concludes with lessons learned and lingering barriers.

Intellectual Property and Food

Clark Wolf

Department of Philosophy, Iowa State University,
Ames, IA, USA

Synonyms

[Patents and copyright](#)

Introduction

Many foods and food crops are covered by intellectual property rules. Intellectual property laws allow people to protect ideas and inventions by preventing other people from copying, using, imitating, importing, or selling the protected subject matter. These protections come in several different varieties, including patents, trademarks, and copyrights, as well as trade secret protections. These rights provide those who possess them, for a limited time, with exclusive claims that cover inventions, discoveries, or original expressions. Intellectual property protections originally applied primarily to mechanical inventions – new machines for moving stones or weaving cloth. As intellectual property law has grown, it has expanded to new areas, to cover different forms of creativity and different products, including foods, agricultural crops, and even living (nonhuman) animals. At present, US law supports

intellectual property protection for bacteria, food crops, animals, and recipes, provided that the inventor can show that the covered subject matter meets other requirements. In the case of patent protection, the covered subject must be *non-obvious*, *novel*, and *useful*. While these laws protect people's interests in ideas – “intangible subject matter,” as it is called in legal jargon – not all ideas are eligible for protection. No intellectual property protection can be given for mathematical formulae, even though they may be difficult to prove. No intellectual property protection can be given for discovery of fundamental laws of nature, even though their discovery may take brilliance and creativity. Several different forms of intellectual property protections cover food or food ingredients, including plants, animals, recipes, and food additives. The following section will discuss different kinds of intellectual property and the different levels of protection they afford.

This entry begins with a brief outline of different forms of intellectual property and the different protections they provide. The second section reviews the major lines of argument that have been employed to justify and defend the various institutions of intellectual property protection. Special controversies that arise in the case of intellectual property protections for foods and crop varieties are considered in the third section, followed by a brief discussion of alternatives to patent and intellectual property protections for food and agricultural products.

Types of Intellectual Property Protection

Intellectual property law includes rules covering patents, trademarks, copyright, and trade secrets (Schechter and Thomas 2003).

Trade secrets include information that an individual or company might wish to keep private, often because this information provides a strategic market advantage. For example, the recipe for a popular food or drink might be protected as a trade secret, because the manufacturer hopes to prevent others from producing and selling an identical product. Trade secrets receive minimal protection,

but are often covered by nondisclosure agreements that constitute a legal barrier to workers who could otherwise sell or reveal the protected information.

Copyright allows authors or publishers to prevent others from making and selling unauthorized copies of written material. The associated rights also include the creator's right to be identified as author of the work and to determine who may revise, adapt, or perform it. For example, most cookbooks are protected by copyright. The associated rights afforded to the copyright holder do not include the right to decide who may use the recipes, but do typically include the right to prevent others from *publishing* the copyrighted recipes.

Trademarks, borne by many food products, are a recognizable sign that uniquely identifies products as being from a particular source. Trademark protects a manufacturers' exclusive right to prevent others from using a designated "word, phrase, symbol, or design, or a combination [thereof], that identifies and distinguishes the source of the goods of one party from those of others" (US Patent and Trademark Office). Trademark protection is not available for generic food terms – for example, one could not get trademark protection for the word "pasta" or "hamburger" – but may be gained for names that are used to distinguish one brand from another, like "Barilla" or "The Fighting Burrito."

Patents are similarly designed to protect against unauthorized copying, but apply to inventions or discoveries that are useful, nonobvious, and novel. A patent holder has the right, for a limited time (often about 20 years), to prevent others from copying or possessing a copy of the patented item. In return, the patent holder is obliged to *disclose* the invention, by providing a full explanation of its nature and the process by which it can be produced. The scope of patent law has broadened over the course of recent decades to include genes, cells, and organisms as well as more ordinary inventions. These extensions are controversial, but have been widely supported by courts in many countries. Most agricultural food crops grown in the United States either are patented or include genes that are covered by patent laws.

Foundations of Intellectual Property Rights

Intellectual property laws are intended to spur innovation and to give inventors control over the fruits of their creative efforts. Some legal systems incorporate the idea that inventors and creators have special *moral rights* to control their creative products. There is a philosophical debate between those, on the one hand, who think that creators have underlying moral rights that are secured by these legal institutions and others who regard intellectual property rights to be entirely created by the laws that are used to enforce them. If the reasons supporting intellectual property rights are *moral reasons* such as justice or fairness, then presumably the rights in question are moral rights as well as legal rights. If the reasons supporting these rights are merely based on expediency or utility, this is sometimes taken to undermine the claim that there are underlying moral rights to be secured.

Intellectual property rights are typically defended on three different grounds: first, they are sometimes defended as *Lockean* rights, following the theory of property described by John Locke in Chapter V of his *Second Treatise of Government*. Second, they are often defended in terms of the "personality interest" that creators have in the control of their creations. Third, these rights are often given a utilitarian defense. Utilitarians urge that the protection of these rights promotes public welfare (Moore 2008, 2011; Hughes 1988; Hettinger 1989; Kuflik 1995).

The *personality defense* of intellectual property begins with the idea that people have a moral claim to their talents. When people invest their creative efforts in the development of new works or ideas, they have, it is argued, a special claim to control the results. Artists, for example, have an interest in defining, within reasonable limits, the uses to which their artworks can be put, an interest which is set back if they have no control over their works. In a similar vein, new recipes invented by creative chefs may be works of art into which the creator has a personality interest, like any other artist. The personality defense of intellectual property is founded on the

view that creators invest their personalities in the works they produce, giving them a right to control these works.

The *Lockean defense* of intellectual property is based on the idea that individuals are entitled to the products they create and in which they invest their labor. Locke argued that, because people have a right to their own bodies, when they improve something's value by investing their own labor into it, they acquire a property right to that thing which justifies excluding other people from using it. However, such property rights only accrue to things that were previously unowned. Thus, on Locke's view, a person who collects pecans from under an unowned tree in the wild would acquire a property right in them, but someone who collects nuts under a neighbor's tree would be a thief.

Finally, the *utilitarian defense* urges that legal regimes that protect intellectual property are good policy because they promote social welfare. They do this, principally, by providing an extra incentive to reward creative work. In many cases, the development of new products requires a significant investment of time and money for research. Protection of intellectual property rights gives creators a period during which they can hope to regain the costs of development and to profit from their creative efforts. By providing an incentive for creative work, an intellectual property regime promotes the development of valuable and welfare-enhancing products and ideas. Some people also see intellectual property rights as a safeguard against people who might "free ride" on the creativity of others by using others' inventions without payment or consent. This view, however, is by no means universal. Other writers, including Thomas Jefferson, have argued that it is a virtue of invention that one person may use another's invention without imposing disadvantage on the inventor. From the utilitarian perspective, wider dissemination of valuable inventions is a good thing. From the perspective of the *personality defense*, however, such dissemination might be interpreted as unjustified theft.

Some forms of intellectual property protection are expressly designed with these utilitarian considerations in mind. Patents, for example, are

often described in terms of the expectation that patent protection represents a mutually beneficial exchange between an inventor/patent holder and the public at large. The patent holder receives, for a limited time, an exclusive right to license and the patented item and to prevent others from making and selling it. (A patent right does not include a positive claim to make the patented invention: where inventions are dangerous or otherwise regulated, even the patent holder may not have a right to make the item). The period of patent protection is supposed to provide the patent holder with the ability to recover research and development expenses and to make a profit. The public receives, in return, access to creative products that would not otherwise be available and free access to the information necessary to produce them. As part of the patent process, the patent holder must *disclose* the invention, by providing complete instructions sufficient to allow another person to make copies of the patented invention. After the patent expires, the invention is in the public domain, freely available for use by anyone.

The alternative different defenses of intellectual property, variously based on personality, labor, and utility, are not mutually exclusive: one might accept that each provides relevant reasons to protect and respect intellectual property rights. But different reasons may be relevant to different circumstances. The personality defense is most plausible for artworks and for other creative products in which creators have invested personal meaning. The Lockean argument is most plausible for creations that can be framed as the fruit of the creators' labor.

The utilitarian argument may be the broadest of all, but has its most central application to inventions that promote the public good. Critics of intellectual property laws often argue that these laws fail to promote public welfare since they prevent people from using valuable information. Defenders urge that the information that is constrained would, in at least some cases, not have existed at all but for the incentive effect of intellectual property law. This incentive effect and the fact that intellectual property rights are typically time-limited are important aspects of the case for the claim that these rights promote public

welfare. After the time limitations on these rights expire, the protected ideas are in the public domain and can be used freely by anyone.

The disclosure requirement, for patents, is another important element of the utilitarian defense. Unless the invention is otherwise regulated, a patent holder typically has an exclusive right to license and sell patented goods and to prevent others from making, selling, or using the patented subject matter without permission or payment. In return, the patent holder must *disclose* the invention by publishing a full account of the invention, including instructions for making it. When the patent expires, other people can use this account to make, use, and sell the item. The idea behind this policy is that inventors invest money, effort, and creativity to develop new technologies. The period of patent protection enables them to earn back that investment and to make a profit on their creative efforts. Inventors are advantaged because they have exclusive rights in their patented subject matter. The public is advantaged because the patented technology is available and publicized. In the absence of patents, inventors might keep their inventions secret to prevent others from copying. Such secrecy is worse for the public, because secret inventions are usually less widely used. And it is worse for the inventor because secret inventions often cannot be sold or produced without disclosing the secret. Critics of intellectual property rights sometimes overlook the fact that keeping information secret is a likely outcome for some products and inventions and that secrecy will often be advantageous when other forms of protection are not available. In such cases, it can be argued that the elimination of intellectual property rights would not immediately make information public and available. Instead, it would drive information underground.

This case may be undermined, however, if there is evidence that intellectual property protections are not being used in the way projected by the laws. Sometimes, for example, people have tried to take out patents on technologies that would otherwise have been available in any case or to patent inventions created by other people. Attempts have sometimes been made to patent ideas that are widely used and understood. And

sometimes, patent protectors become “trolls,” the term used for people making money by suing people who use the technology covered by their patent, without marketing the patented product themselves. In such cases, intellectual property protections can lock up inventions by moving them out of the public domain, preventing or slowing creativity instead of promoting it.

Intellectual Property Controversies in Food Ethics

Some of the earliest examples of intellectual property protection covered food items. Moore (2011) reports that “chefs in the Greek colony of Sybaris were granted year-long monopolies for creating particular culinary delights.” Presumably, the purpose of this brief protection was to provide an incentive for creative cookery. More recently, there has been a surge in intellectual property protection for foods, especially patents on mass-marketed food products. US patents have been granted for foods with novel properties, including longer shelf life, flavor, nutritional value, appearance, and many others. Some of these patents are controversial for one reason or another. Sometimes patents are granted for information that should properly be in the public domain, in which case the patented item can no longer be freely used. Some people have other reservations about patented material, arguing that some kinds of things – including some intangible subject matter – should not be privately owned. Some people object on moral grounds to the technologies that are covered by patents. And it is sometimes argued that intellectual property protections improperly give to corporations or individuals control over food or agricultural production.

Patenting in the Public Domain? If the material is already in the public domain, it is not properly patentable subject matter. Patent law was not intended to remove valuable intellectual property from the public domain, but sometimes patent examiners make mistakes. Examples of errors, in this case, are controversial, but sometimes errors are recognized, and patent protection is rescinded.

For example, one highly controversial patent (US Patent Number 6004596) covers:

A sealed crustless sandwich for providing a convenient sandwich without an outer crust which can be stored for long periods of time without a central filling from leaking outwardly. The sandwich includes a lower bread portion, an upper bread portion, an upper filling and a lower filling between the lower and upper bread portions, a center filling sealed between the upper and lower fillings, and a crimped edge along an outer perimeter of the bread portions for sealing the fillings therebetween. The upper and lower fillings are preferably comprised of peanut butter and the center filling is comprised of at least jelly. The center filling is prevented from radiating outwardly into and through the bread portions from the surrounding peanut butter.

This patent covers peanut butter and jelly sandwiches with certain special properties: to violate the patent, a sandwich must have its crust removed and edges crimped. In addition, there must be two separate layers of peanut butter to prevent the jelly from coming in contact with the bread, making it soggy. The examiner who approved this patent must have judged that this technique would not be obvious to experts “skilled in the art” of sandwich making. Non-obviousness of this kind is a requirement for patent eligibility. The fact that crustless peanut butter and jelly sandwiches are common in lunch boxes around the country has been cited as evidence that this patent was improperly granted (Jaffe and Lerner 2004).

Another similarly controversial case involves US Patent 5894079 issued to cover a species of bean called by the patent holder as the “Enola bean” (Wolf 2007). The patent identified the bean by its species and color, but it was later discovered that beans with the same properties had been in use in the United States prior to the issuance of the patent and that they had been in use in Mexico for hundreds of years. The Enola bean patent was challenged and rescinded, but the process required to challenge patents is expensive and time-consuming. Unless people are willing to spend the necessary resources to challenge them, such patents are likely to remain in effect.

Patenting What “Should Not Be Owned” It has sometimes been argued that plants and crop

species should not be patented, because, as some people believe, they should be regarded as part of the common heritage of humankind (Magnus 2002; Ossorio 2007). The claim is that plants and living organisms are automatically in the public domain so that private appropriation of them is a kind of theft. This argument is more tenuous when it is applied to crop varieties that have been carefully developed, whether by selective breeding or by direct genetic manipulation. In such cases, the organism developed may be quite different from the original, and there are good reasons to think that the kind of development work undertaken by plant breeders and geneticists is just the kind of work intellectual property rights is intended to promote.

Patenting Controversial Technologies Some critics of agricultural patents, however, regard some of the patented products to be morally questionable whether they are properly regarded as inventions or not. Critics of agricultural biotechnology, in general, and genetically engineered food crops, in particular, often argue that these technologies should not be covered by intellectual property rights because they are dangerous to humans or to the environment or because they find such technologies to be intrinsically wrong. Under US law, however, the claim that a technology is morally reprehensible is not regarded as a legitimate reason not to issue a patent. If patented subject matter is *dangerous* or if its production would violate other people’s legal rights, then the state may prohibit the patent holder from making the invention covered in the patent. For example, a chef who invented a new recipe for cooking endangered animals might be able to get a patent on the recipe, but no right to possess or kill or serve the endangered plant or animal. In such a case, the fact that the recipe cannot legally be made would not necessarily prevent a patent from being issued. But in general, the fact that a technology is regarded to be morally questionable is not a valid legal reason to deny patent protection. One might find this to be at odds with the thought that patents and intellectual property rights in general are supposed to incentivize the development of valuable new technologies: how

can patenting immoral inventions promote the public good? But in a pluralistic society, different people hold different moral values and might not agree on which inventions are morally questionable. Patent examiners are not qualified to make judgments about the morality or immorality of the inventions they review.

Patents and the Control of Food and Agriculture Still others regard agricultural and food patents to be morally problematic because they enable corporations to control the behavior of farmers, cooks, and eaters. Still others worry that agricultural patents may leave people hungry or otherwise exacerbate food security concerns, since they constitute a kind of proprietary control over the food supply (Tansey and Rajotte 2008).

One context where this problem arises is *seed saving* by farmers. Before agricultural varieties were patentable, farmers were able to save seeds from 1 year to the next and did not rely on corporations to provide seed. Those who grow crops covered by patents or other intellectual property protections, however, cannot save and replant seeds without violating the terms of the patent. Farmers can still grow non-patented seed varieties, which are in the public domain. But patented crop varieties often have features farmers want, including pest or herbicide resistance, higher yields, or other desirable agronomic properties. Defenders of patents note that these desirable properties are present because of the research and development done in pursuit of the patent. The crop varieties that possess them, therefore, are significantly different from the varieties that are in the public domain.

It is a different matter if the patented crops or traits were developed, in part, at public universities with public funding. In such cases, it may be inappropriate for a private individual or corporation to gain control over the patented variety, since this would involve the conversion of public funding for private benefit (Streffler 2006).

Agricultural patents have changed the power relations involved in food production in other ways as well. At one time, farmers were mostly independent, reliant only on their own resources and the fertility of soil and weather. Present

market conditions have been significantly created by intellectual property laws, and farmers must work within these strictures. The existing system allocates enormous market power to large agribusiness companies and less power to farmers. Some people urge that this situation renders farmers vulnerable to exploitation or that it is an intrinsically unjust distribution of power.

One major issue involves the containment and “adventitious presence” of patented crop varieties. When patented crops migrate and replant themselves, who should be held responsible? Current patent law regards possession of patented subject matter as sufficient for the charge of patent violation, even in cases where the patented item was not used. This provision makes sense for machines and software and in general for inventions that do not replicate and distribute themselves. It is much more controversial in the case of plants. In a widely discussed Canadian Supreme Court case, *Monsanto vs Schmeiser* (2004), Percy Schmeiser, a Saskatchewan canola farmer, was sued by Monsanto corporation for patent violation when patented glyphosate-resistant canola plants were found in his field. He argued that the patented material arrived on his field by pollen drift and that he had never used the protected patented trait. The Canadian Supreme Court noted that possession of patented subject matter constitutes violation even in the absence of use. In such cases, the law does not distinguish cases where the possessor of the patented item intentionally acquired it or acquired it involuntarily, as Schmeiser claimed. The court sidestepped the issue, however, ruling that Schmeiser had taken positive steps to acquire Monsanto’s patented product and that he had used glyphosate expressly to select for the patented trait. Current US and Canadian laws leave open the possibility that land owners may be liable for patent violation when patented plants migrate onto private property. Some commenters are undisturbed by this feature of patent law and note that involuntary patent violators might have a cause of action against their neighbors in such cases. They recommend that the possibility of involuntary patent violation should not motivate a change in patent law (Janis 2002). It would be a

significant disadvantage for property owners, however, if they must endure a lawsuit from a patent holder, even if they can regain some of the loss by suing the neighbor whose field was the source of the patented germplasm. It is likely that patent law will continue to evolve in response to these problems involved in the containment of patented crop varieties.

Alternatives to Intellectual Property

Where intellectual property protections are not available, innovators have three choices: (1) they can make their creative products freely available to everyone, in the public domain; (2) they can keep their inventions secret; or (3) they can find alternative means to control their products.

Public Domain If new products immediately enter the public domain, this would undermine the incentive effect of intellectual property law, which is intended to spur creative invention. But, while intellectual property laws provide an incentive for both creativity and disclosure, there is no reason to think that creative efforts would cease if these laws were not in place. Some kinds of creative work, however, require many years of costly investment in research and development. For example, the development of a new crop variety typically requires 10–15 years for development, and the research involved may cost millions of dollars (Sease and Hodgson 2006, p. 350). Creative efforts that impose these heavy costs might be less likely in an environment where protections are not available.

Secrecy Critics of intellectual property sometimes argue that ideas should be freely available to everyone, but the elimination of the laws protecting intellectual property would not immediately make ideas free. Some inventors would simply keep their inventions secret. Many creative products are already maintained as secrets, instead of being made available in the public domain. Secrecy is not necessarily better than public disclosure: patented creations are available for others

to study, even during the period when they are protected as private property.

Alternative Means In the absence of intellectual property laws, it is sometimes possible for people to protect their creative products in other ways. Some seed companies include license restrictions on seed bags that itemize restrictions on replanting or require growers to sign a technology agreement when purchasing seed. In this way, they are able to use contract law to restrict growers' legal right to save seed and replant. While contract law can be used to replicate *some* features of intellectual property protection, however, it cannot replicate them all. Contractual agreements apply only to those who sign or otherwise consent to their terms, while standard intellectual property protections imply obligations for everyone, not just to consenting contractors. But some crops are effectively protected when desirable traits are not heritable by the next generation or when biotechnology is used to restrict the possibility of seed saving and subsequent planting. For example, hybrid crop varieties are effectively protected since seeds saved from hybrids will not grow into plants that have the desirable agronomic traits and high yields of the originals. And some companies have worked to develop "genetic use restriction technologies" (GURTs) that effectively accomplish the same thing. The so-called "terminator" technology makes next-generation seeds sterile, insuring that farmers cannot save and replant patented seeds. This technology is highly controversial and is not presently in use.

Summary

Because intellectual property rules allocate advantages and constraints, they will always be controversial. Since some ways of distributing these advantages and constraints are morally better than others, the problem is one of ethics and justice, not just efficiency. These rights are designed to reward creativity and to provide incentives to promote research and development of new ideas. Some ethical controversies associated with intellectual property law arise when the

laws are misused. Other ethical controversies arise as a result of the way the institutions are structured. Food is a fundamental human need, and agricultural food production is an enormous undertaking. For this reason, it is especially urgent to ensure fairness and equity in the distribution of intellectual property rights in these areas.

Introduction: New Agro-technologies Require New Legal Protection

For thousands of years, new seeds and new foods have been exchanged and traded without any legal

regulation of intellectual property. Huge improvements in seed breeding resulting in increased harvests (like the ones resulting from the so-called Green Revolution in the 1960s) have been achieved just by “brown bagging,” sharing, experimenting, sometimes stealing, and imitating. However, at the end of the 1970s, biotechnology was increasingly perceived by governments as an exciting field of technological innovation that would lead to renewed economic growth and restore international competitiveness for western countries. The huge economic potential of this new field of technology would however only be unlocked, so it was thought if biotechnological inventions were to receive proper legal protection. In the landmark case of *Diamond v. Chakrabarty* concerning the patentability of a genetically modified oil-consuming bacterium, the US Supreme Court ruled in 1980 that “anything new under the sun that is made by man,” whether living or nonliving, can be patented. In subsequent years, US jurisprudence explicitly extended patentability to multicellular organisms like plants (1985), oysters (1987), and mammals (1988). Other western countries ultimately followed the American example, albeit with some delays and hesitations. In 1988, the patent offices of the USA, the European Union, and Japan proclaimed the new policy line that DNA sequences and genes would also be eligible for product patents. Their justification was that sequences and genes, when isolated and purified, would be essentially different from their natural counterparts and therefore qualify as inventions rather than discoveries. However, soon many raised ethical objections against this type of legal protection because it implies an unacceptable form of exclusion of the many poor farmers that cannot afford to pay for the patents.

Globalization of Breeders’ Rights and Patents

In a parallel move, the legal protection of plant varieties resulting from conventional breeding by so-called plant breeders’ rights would also be tightened up. In 1961, a handful of western

(mainly European) countries had concluded the first international agreement on plant variety protection, called UPOV, after its French acronym (*Union internationale pour la protection des obtentions végétales*). This agreement gave the originators exclusive rights on commercializing their plant varieties, but granted other breeders the right to use these varieties as starting material for further breeding (breeder’s exemption) and left farmers the freedom to save seed from their harvest for the next planting season (farmer’s privilege). In 1991, a new international agreement was concluded (referred to as UPOV 1991), which drastically curtailed the breeder’s exemption and virtually annulled the farmer’s privilege, bringing plant breeders’ rights more in line with patent law.

In the eyes of its main beneficiaries, the intellectual property regime also needed to be globalized. Driven by an influential business lobby in the pharmaceutical, biotech, and entertainment industries, the US and European governments used their clout in international trade negotiations to “persuade” reluctant developing countries to accept the (for them often disadvantageous) terms of the *TRIPS agreement*, which was concluded in 1994 as part of an overall WTO package. The TRIPS agreement (standing for *Trade-Related Aspects of Intellectual Property Rights*) sets worldwide minimum standards for the protection of intellectual property rights (including patents, copyright, and breeder’s rights). It mandates that, with few exceptions, “patents shall be available for any inventions, whether products or processes, in all fields of technology” (art. 27.1). Countries are allowed to exclude plants and animals (other than microorganisms) from patentability, but “Members shall provide for the protection of plant varieties either by patents or by an effective *sui generis* system or by any combination thereof” (27.3b). Breeder’s rights are an example of a *sui generis* system of plant variety protection. Many developing countries have meanwhile joined the UPOV 1991 agreement to fulfill their TRIPS obligations. In the USA and the European Union, genetically modified crops may even be doubly protected by patents and by plant breeder’s rights.

Criticism: IPRs and Food Security, Traditional Knowledge, Environmental Sustainability, and Social Justice

Particularly in the life sciences, IP rights regulate objects such as food and medicines that are key to securing human rights, especially the right to adequate food and the right to health (Universal Declaration of Human Rights, UDHR 25.1). Consequently, IP serves private and public interests. The private interest consists in being able to enjoy the fruits of one's labor, and the public one is about the provision of current and future public goods. Extensive research and development (R&D) enterprises are made profitable as rights holders can market their products exclusively, securing the existence of new commodities and due to the temporary nature of IP, also the provision of future public goods, as the invention becomes part of the public domain. Nevertheless, criticisms abound.

Firstly, the current IPR regime provides according to many insufficient incentive for providing innovations that will alleviate the problems that predominantly affect the poor and to make those innovations widely accessible. European states have a long-standing tradition in securing for their citizens the minimum requirements for an adequate living standard. The success of eradicating extreme poverty in Western Europe has not only lead to viewing this harm to human welfare as something that is unacceptable but also as preventable. As the sums needed to alleviate this welfare burden globally are relatively low compared to other expenditures made in developed countries, not helping is seen as an unacceptable moral menace by a growing percentage of the citizens of developed and developing countries.

With the excessive income inequalities all over the world, it is evident that if the economically worse-off people, such as farmers, are not allowed to make use of the technological innovations of developed countries, they will end up even poorer (Korthals 2010). Furthermore, objects predominantly needed in resource-scarce markets will not be developed, as R&D expenses cannot be recovered (DNDWG 2001; CIPIH 2006).

The right to adequate food and the right to health (Universal Declaration of Human Rights (UDHR), article 25.1) are not the only two human rights that collide with liberties granted by the use of exclusive rights secured by IP regimes. There is a strong plea for a democratization of science, a demand for openness and inclusion, both in active participation and decision-making, elements that in the human rights discourse are encompassed in the right to share in the advancement of science (UDHR, article 27.1). There is a widespread indignation about the way the current IPR regime restricts freedom to operate and a perception that high-level science is treated as a luxury reserved for the developed world alone.

Secondly, as costs of bringing out a saleable product in the life sciences have constantly risen, a stricter market orientation has become even more mandatory, with the effect that industry mergers were seen as necessary in providing goods in the food and health sector. Patents have actually been key drivers behind the increasing economic concentration (and vertical integration) of the global agrifood industry (Glenna and Cahoy 2009). Often, goods that were formerly free, like seeds, have now to be paid for by end users due to high product development expenses. The current system has the unintended consequence that increasingly larger-scale players dominate the markets, with a foreseeable adverse effect on the rate and quality of inventions and the survival of small and medium-size enterprises. Here, particularly newcomers from the developing world face a difficult start.

Thirdly, there are up to this moment unresolved issues like how indigenous knowledge should be treated and in what way biodiversity should be maintained, as well as questions concerning the regulation of biosafety dossiers. It has to be assessed to what extent those issues should be addressed by IP regimes themselves, or in how far the existence of these regimes has created a situation that demands those issues to be dealt with. The first two subject matters are often brought under one umbrella as interests of the developing world. Biodiversity is often seen as something that is vital, but there are insufficient

empirical studies that provide clear evidence that industry needs biodiversity as much as commonly stated. Success in conserving (or even enhancing) biodiversity depends very much of the outcomes of such studies, as such evidence is a huge leverage for bargaining deals for its protection and the establishment of proper incentives therefore. Something similar holds for traditional knowledge. Stating its importance as cultural heritage of mankind might not be enough to find sufficient infrastructural support – studies showing how industry has benefited from traditional knowledge will help to gather a much wider involvement in initiatives that seek to conserve and recognize indigenous scientific practices and knowledge.

Fourthly, evidence on the possible negative effects of the current IP regime and on the potentialities is difficult to acquire. One of those negative effects is that the system of protecting intellectual property has become extremely expensive, in its demand of researcher's time and resources. A wide contingent of legal experts has to be financed by reallocating funds originally destined for research and development. Another regards the one-size-fits-all approach propagated with the TRIPS agreement, which might be less suitable for innovations in the life sciences than for promoting research and development in the electronic, chemical, or mechanical industry. Inventing around is in many cases not possible due to the very nature of life organisms. As inventions in this area could help to secure the human rights to adequate food and health, optimizing the incentive system is imperative. Here, one cannot just trade off business opportunities lost in one area against other ones; a detailed assessment on the unused potential to secure human rights has to be made. Many important stakeholders feel that their interests and voices are not being taken into sufficient consideration in negotiation rounds and the drafting of IP laws. Justice demands more than a fairer distribution of objects of innovation and the availability of biotechnological solutions for the problems that the poorest people in the world are predominantly confronted with. Being able to participate at all levels of the innovation process and having a say on research agendas are something completely out of reach for most of the

world's population. For some human rights advocates and scientists, wider participation cannot be even sacrificed for higher efficiency in making technologies available to more people, this coming in line with what is known as the right to share and participate in advancement and benefits of science in the human rights discourse.

Patenting and the Global Spread of GM Crops

Transgenic crop varieties were first commercialized in 1996. Since then, a suite of different GM crops have spread to different parts of the world in a rather uneven pattern, determined by varying socioeconomic and agroecological conditions but also by different regulatory frameworks and intellectual property arrangements. The area planted with biotech crops has increased 94-fold from 1.7 million hectares in 1996 to 160 million hectares in 2011 (ISAAA 2011). The two traits that have most often been inserted into GM varieties are herbicide tolerance and insect resistance. The main agricultural crops involved are soybean, canola, maize, and cotton. Transgenic crops are mostly grown in North and South America and in Asia (especially China and India), while Europe and Africa are the continents with a very low adoption rate in terms of the number of approved varieties as well as of planted area (Wallace 2010). Adoption may be influenced by the vicissitudes of intellectual property protection and biosafety regulation, as is illustrated by the case of GM soybeans in South America. At an early stage, Argentina eagerly adopted the so-called Roundup Ready soybean, which had been developed by the US company Monsanto as a GM variety resistant to its proprietary herbicide glyphosate (trade name "Roundup"). The variety was actually without legal protection in Argentina and therefore formally in the public domain, as Argentine law did not allow patents on plants, and Monsanto had failed to apply for a plant breeder's right (Correa 2006). This did not prevent Monsanto to claim royalties from Argentina for the use of its "proprietary technology." The US company even went so far as to seize shiploads of Argentine soy meal in

European ports and sue for patent infringement there (in the end, European courts rejected Monsanto's claims). Through illegal smuggling from Argentina, glyphosate-resistant soybeans also reached farmers in Paraguay and Brazil, where the new GM variety had not yet been approved by the regulatory authorities. Widespread adoption by farmers in those countries created a fait accompli, which was subsequently legalized by a formal approval not based on a careful biosafety assessment. Something similar happened in India with insect-resistant Bt cotton (containing a gene from *Bacillus thuringiensis* that produces a toxin against insects). This variety had been developed by Monsanto and its Indian subsidiary Mahyco. These companies proved unable to retain their intellectual property control over the new variety, after Gujarat farmers had somehow appropriated the transgenic seeds (possibly from testing fields), crossed it out with indigenous varieties, and in the process created a huge market for "stealth seeds" (Herring 2007).

Tangible Property and Intellectual Property

Biotech companies attach great importance to *respect for intellectual property*. For them, patents and plant breeder's rights are a just reward for their inventive efforts and allow them to recoup the costs and expenses incurred in creating new GM varieties. Hence, they very much lament any unauthorized use of "their" technologies, for example, by farmers who grow "pirated" GM crops without paying them any royalties. Although patents, plant breeder's rights and other intellectual property rights are territorially based, it is striking that companies tend to see their inventions as proprietary also in those countries in which no patents or breeder's rights have been filed. Thus, Monsanto claims royalties on the use of GM soybeans in Argentina even though their invention is not legally protected in that country. It is also not unusual for biotech companies to magnanimously "donate" their technologies to humanitarian initiatives for use in countries where they have no markets (as with the WIPO

Global Responsibility Licensing Initiative), but what exactly do they give away if they have no patents in such countries in the first place? For farmers, property rights are also at stake, but their concern is rather that modern *intellectual* property threatens to erode their *tangible* property. In the old days, when a farmer bought seed from the seed merchant, it truly became his property, that is, he could do with it whatever he liked. He could use it to grow his crop and save seed from the harvest for replanting in the next season (or he could exchange it with his neighbor or even sell it on the market). New interpretations of patent law, followed by a drastic revision of plant breeder's rights (UPOV 1991), no longer allow on-farm seed saving. When a farmer buys GM seed from a biotech seed company, it no longer becomes his full property because he no longer acquires the right to make use of an inherent biological characteristic of the seed, i.e., its natural capacity to reproduce itself. In fact, it would be more appropriate to say that the farmer "rents" the GM technology incorporated in the seed for the duration of only one growing season.

While biotech companies demand respect for intellectual property, others fear that the *autonomy* and *independence* of farmers will be increasingly undermined by more stringent IP restrictions on saving seed. The famous report on the International Assessment of Agricultural Knowledge, Science and Technology for Development (IAASTD) expresses "concern about present IPR instruments eventually inhibiting seed-savings and exchanges" (IAASTD 2008, p. 42), thereby restricting the capability of farmer communities to develop locally adapted varieties and to maintain gene pools through in situ conservation – essential to local practices that enhance food security and sustainability.

Patents, the Herbicide Treadmill, and the Shrinking of the Public Domain

There is a further reason to be cautious about claimed and expected public domain benefits of patenting GM crops. That reason may be summed up in the slogan: *Nature fights back*. One of the

first things biotech companies did was to develop crops that would be resistant to their proprietary herbicides, a strategy that makes economic sense given the patentability of both GM crops and herbicides (Harhoff et al. 2001). Thus, Monsanto created GM “Roundup Ready” varieties of canola, maize, and soybean that tolerate its registered herbicide “Roundup” (glyphosate), a strategy that was quickly followed by its competitors Syngenta, DuPont, Bayer, and BASF. Continued and widespread use of certain herbicides, however, acts as a selection pressure favoring the spread of resistant weeds. What is currently happening in US soybean and maize cultivation is a case in point. Monsanto’s “Roundup Ready” (glyphosate tolerant) crops have been immensely successful in the USA, where they currently cover 90% of the soybean area and 80% of the maize area. In comparison with some older and more aggressive herbicides, glyphosate is relatively benign in its effects on wildlife. Many successive years of glyphosate use, however, have now resulted in at least nine nasty weed species that have gained immunity to this herbicide. The expectation is that by 2015, some 40% of the cultivation area will harbor resistant weeds. Farmers have to resort to older and less ecologically benign herbicides such as 2,4-D and dicamba, in addition to using Roundup, to kill the new invaders. Agrochemical and biotech companies are meanwhile developing new herbicide-tolerant varieties of soybean and maize with “stacked” transgenes that will not only tolerate glyphosate but also other herbicides. This ongoing “arms race” between biotech and nature may not be too bad for some of the biotech companies involved, but illustrates that environmental benefits of agricultural biotechnology are sometimes only temporary rather than durable or truly “sustainable.” A cynic might even argue that the evolution of weed resistance makes highly successful herbicide-tolerant cultivars obsolete over time, thus clearing the way for new cultivars to enter the market and decreasing the chance that an effective invention reaches the public domain as a generic cultivar after the end of the patent term. For a company like Monsanto, of course, the emergence of glyphosate-resistant weeds when

its patents on glyphosate-tolerant crops are about to expire is not something to be deplored (although company scientists had earlier dismissed this possibility as highly improbable). This process of creative destruction favors private “innovation” (for a similar view that antibiotic resistance favors pharmaceutical innovation, see Outtersen 2009). Industry scientists claim that the use of new transgenic crops with stacked tolerance traits for glyphosate and other herbicides like 2,4-D and dicamba is not likely to accelerate the evolution of multiply resistant weeds, but other researchers argue that sooner or later the emergence and spread of such superweeds are precisely an outcome that is to be expected (Mortensen et al. 2012). The whole agricultural system seems to be set on “accelerating the transgene-facilitated herbicide treadmill” (*ibid.*, p. 83). Unfortunately, the knowledge infrastructure needed to practice Integrated Weed Management, which would enable farmers to escape from this treadmill, is simultaneously atrophying because the relevant type of knowledge does not lend itself to being packaged in patentable and saleable products (*ibid.*, pp. 81–82).

The emergence of resistant weeds as a “natural” response to the widespread use of herbicides on herbicide-tolerant GM crops and the concurrent atrophy of Integrated Weed Management thus call the rationale of the patent system into question. The obsolescence of transgenic crops at the end of the patent term due to the evolution of weed resistance also vitiates a key justification for the protection of intellectual property. The underlying idea of the so-called patent bargain is that in applying for a patent, the inventor receives a *temporary* monopoly on exploitation in return for disclosing his invention and that after the expiration of the patent term his invention will fall into the public domain. It now transpires that once it becomes available for free public use, the invention may have almost entirely lost not only its economic value but also its technical efficacy. Even more, a patent may induce its owner to socially *waste* a finite resource, to wit, the depletable effectiveness of means for crop protection.

Patents and Climate-Ready Crops

A special case, because of its urgency, is the role of patents regarding the innovation process of crops that can accommodate or even reduce climate change. As is well known, most poor countries are more vulnerable to climate change than the rich ones, due to their location but also due to the fact that they are more dependent on agricultural production in earning their livelihood. Developing new technologies for pro poor innovation requires focusing on crops that are important in the poorest parts of the world, such as sorghum, millet, chickpeas, and groundnut; however, research agendas of industrial companies have neglected these almost entirely for understandable economic reasons. The current IPR regimes determine research agendas that are not conducive in reducing poverty and accommodating to climate change in the poorer areas.

Alternatives for the Current IPR Regime and Unfair Trade: Open Source, Open Access, and Food Impact Fund

There are at least three alternatives (or complements) to the current IPR regimes covering production, participation, and consumption of knowledge. “Open innovation” does not mean for free, but free in the sense of being transparent and unrestricted – business models are compatible with open innovation. The question if more openness leads in itself to fairer distribution is something that remains unresolved until further research. Many emphasize the role of commons for the future production of knowledge and their potential to rebalance uneven power relations (Jefferson 2006).

The second, “Open Access” (Krikorian and Kapczynski 2010), covers two currents in the access to knowledge movement, one that aims to build an information society where knowledge is openly available without restriction at all and the second that seeks a general expansion of the public domain. These currents are in particular relevant for initiatives for protecting traditional knowledge through exclusive rights. The attempt

to protect traditional knowledge by exclusive rights is at odds with approaches based on sharing rather than appropriating knowledge. The compatibility of predominantly western conceptions of intangible property with customary laws and the extent to which they adequately consider the static and dynamic nature of traditional knowledge are rather unclear.

The third approach aims at an “Impact Fund” (Pogge 2008). Linking profits to positive impact on alleviating an urgent problem is of particular interest for targeted products not covered sufficiently by market incentives, such as medicines for so-called neglected diseases or improvements in seed varieties especially targeted for the needs of the poor. The idea behind the fund is to offer a reward to companies that aim at maximizing quality-adjusted life years (QALY) of people suffering a disease or disorder. While retaining its IP rights, the company has to commit itself to sell the medicine at cost price in order to be rewarded monies proportional to the impact in increasing QALY its medicine has. The main criticism of the impact fund idea questioned the prerequisite of patents for fund rewards and its maintaining of current power relations.

Summary

The patenting of biological inventions thus raises special ethical issues. The main issues are:

- (a) What can be the socially desirable balance between types of exclusivities innovative enterprises require and the inclusive public goods protection it is said to serve? How is this proper balance to be achieved?
- (b) What old and new ideas (such as Open Source and the Access to Knowledge movement) about exclusivities such as protection and property and their optimal integration with the public good of human welfare, fair trade, and fair invention are interesting and worthwhile for debate and experimentation? What pilot studies should be pursued?
- (c) In what way can an intellectual property rights system become inclusive, not only listening to

the voices of patent holders but also to those stakeholders that are affected by the patent system?

- (d) How can inventions be stimulated that are specifically designed to alleviate urgent problems and to reach global targets, such as the millennium development goals and caps in climate change gases emissions?
- (e) Why are the flexibilities of TRIPS agreement regarding human welfare (TRIPS, art. 6) not often used in national regimes, and why does the full potential of TRIPS seem to be under-used? Which steps can be taken to ensure better use of those flexibilities?
- (f) How can ethical principles and values of a nation or a group of nations be protected, and what does this mean with respect to a broad interpretation of *ordre public* and public policy exemptions to patentability (TRIPS, art. 27.2 and 27.3)?

International Food Quality Standards

Neal H. Hooker

John Glenn School of Public Affairs, The Ohio State University, Columbus, OH, USA

Synonyms

[Codex alimentarius](#); [Food safety](#); [WTO](#)

Introduction: Why and Who?

Various aspects of food quality can be controlled, coordinated, certified, and communicated by government agencies, third parties, supply chain contracts, and voluntary standards. Such quality standards can increase the value, volume, and

nature of agricultural and food trade across international borders. Indeed, certain ingredient supply chains or stages of processing may span multiple countries. Imports and exports might be inspected and acknowledged to meet a particular standard, highlighting a product quality attribute or a process step. Any such coordination of national-level food quality standards can be called *rapprochement* (Hooker 1999). Regulatory rapprochement is the process of attempting to establish harmonious intergovernment relationships. The goal is, at best, freer trade without sacrificing consumer protection or, at least, the prevention of food quality standards from becoming a serious point of contention and conflict in international trade.

The World Trade Organization (WTO) uses two key trade agreements (Sanitary and Phytosanitary (SPS) and Technical Barriers to Trade (TBT)) to facilitate such regulatory rapprochement. These agreements recommend the increased use of guidelines adopted by international food quality standards organizations such as Codex Alimentarius (Codex), the International Plant Protection Convention (IPPC) and its regional affiliates (e.g., the North American Plant Protection Organization (NAPPO)), and the International Office of Epizootics (OIE). Countries then have the ability to set stricter food quality standards if they have sufficient scientific evidence that such measures are justified and notification is provided to other countries. This places the burden of proof on the importing country. Conversely, in proving the equivalency (in terms of the resultant food quality target) of differing national-level regulatory regimes, the burden of proof is placed on the exporting country.

The SPS Agreement of the WTO captures this in an important statement of principle:

Reaffirming that no Member should be prevented from adopting or enforcing measures necessary to protect human, animal or plant life or health, subject to the requirement that they are not applied in a manner which would constitute a means of arbitrary or unjustifiable discrimination between Members where the same conditions prevail or a disguised restriction on international trade. (GATT-SPS 1994, p. 1)

The issue of dynamics in international food quality standards is critical. The ultimate goal is to adjust each food quality standard as more scientific evidence, production or processing innovations, and customer and consumer acceptance allows. Discussions of standard levels, the manner that standards are updated, and comparisons of national standards should be done in light of an increasing knowledge of the food quality assurance and management capabilities and the scale of international trade impacted. Demand for higher-quality food products expands as national income rises, leading to calls for stricter standards, suggesting one dynamic that must be accommodated. However, “luxuries” of high-income countries may be at the expense of lower-income countries. For example, trade between developed countries could be well in excess of a minimal (e.g., Codex-based) standard but at the Codex level for goods traded between lower-income countries. Thus agri-food products crossing international borders may still be of very different quality with little more than a “harmonized” minimal standard for a limited volume of trades. This affects each nation’s welfare differently. Higher-income countries rarely accept imports of a lower standard than currently found domestically or from other imports, whereas lower-income countries may see their domestic food quality standards dramatically rise to maintain export income from food trade. Alternatively, a segmented market may see high-quality products exported with lower-quality foods remaining for the domestic market. This may be at the expense of many local inhabitants, incurring high compliance costs. Therefore, an adjusted international food quality standard though of little or no significance to developed nations could dramatically affect developing countries (Otsuki et al. 2001).

Food Quality Targets: What and Where?

Food quality is multidimensional, made up of a bundle of characteristics or attributes that determine the product’s performance relative to its price. There is no definitive list of food attributes; important product and process characteristics vary

across food categories, consumers, and nations due to risk and preferences. Several important subsets can be identified: Safety attributes include foodborne pathogens, heavy metal and pesticide residues, food additives, naturally occurring toxins, and veterinary drug residues. The second set of attributes relates to the nutritional profile of the product and includes aspects such as fat content, calories, fiber, sodium, vitamins, and minerals. A third subset is value attributes. This is a diverse list that includes characteristics of the product itself that are of value to the consumer but are not food safety or nutrition attributes. Examples are purity (lack of nonhazardous contaminants), compositional integrity (i.e., lack of economic adulteration – replacing cheaper ingredients without notification), size, appearance, taste, and convenience of preparation. The fourth subset is package attributes, which includes package materials, labeling, and other information provided. A fifth subset groups quality attributes that arise from the manner of production and processing of the food or agricultural ingredients. Frequently controversial, these attributes include biotechnology, organic, sustainable, nanotechnology, and irradiation.

As noted, this classification is neither definitive nor exhaustive but is intended to be useful in discussing food quality issues. Particular international food quality standards may embody characteristics from more than one attribute subset. For example, organic food may be appealing to some consumers for its real or perceived safety, nutritional, value, and process attributes. These foods can be identified via package information disclosures supported by traceability regulations (whether mandatory or voluntary) throughout the supply chain. Third-party certification organizations in the source or destination nations may be public or private entities. Important institutional and supply chain differences exist in the nature of international food quality standards targeting raw agricultural ingredients and consumer-ready food products and traceability (Souza Monteiro and Caswell 2010). Generally, as a product moves from bulk to packaged form, more international food quality standards likely play a role. This attribute language highlights the interaction and

interdependency of the various aspects of international food quality standards.

Many recent developments in the adoption of food quality management systems represent a switch toward the application of joint or holistic metasystems and meta-standards where one certificate assures compliance with a set of food quality standards (Caswell et al. 1998). This follows similar trends in other nonfood industries, with efforts focused on reducing product waste, complying with contractual requirements, responding to consumer demands, managing risk, and demonstrating that technical product and process standards are being met. A common though not exclusive incentive for adoption of these systems in the food industry is the management of food safety attributes particularly when traded internationally. Such food quality metasystems include those mandated by governments through regulatory requirements, those adopted voluntarily by companies, and a third type of system – quasi-voluntary. The latter systems are those that are required by such a large proportion of the market as to become *de facto* required standard operating procedure. These systems are quasi-voluntary in that a supplier can choose not to comply and simply not do business with the buyer. However, if they are widely used or are used by important buyers, suppliers may have little choice in whether to produce or process to the specifications.

When considering the role of international food quality standards, it is important to recognize the role of information asymmetry. Product quality can be usefully categorized as search, experience, and credence in nature. Search attributes (product size, ripeness, price) can be fully determined prior to purchase or use and therefore easily controlled, certified, and described via value attributes such as standards of identity, ingredient minimum standards, or labeling. In an international trade context, the role of food quality standards addressing search attributes is to assure that the claimed food quality is correctly presented prior to purchase or progression through the supply chain. The true presence and extent of experience attributes, alternatively, can only be determined after consumption or use, whether by

a downstream customer such as a food processor or the final consumer. Examples include taste, shelf life, and the presence of large physical contaminants and certain forms of economic adulteration. Elements of international food quality standards that attempt to minimize the role of experience quality uncertainty across national borders include audits of the production/processing environment by government or third-party agents and random compliance checks to “test” product quality (if this can be used to determine a valid representative sample of the batch or shipment). Whereas search quality uncertainty suggests the primary role of international food quality standards is to ensure all salient information is complete and accurate and made available prior to purchase, for experience uncertainty the goal is to strengthen trust and credibility through guarantees of quality assurance, consistency, and remediation in times of poor quality. Finally, credence quality uncertainty cannot even be resolved after use or consumption. Common examples lie within food safety and nutrition characteristics. Microbial pathogen or pesticide residue content cannot be determined without complete product destruction. International food quality standards attempting to mitigate credence uncertainty are traditionally in the domain of mandatory, public, and direct regulation (Caswell 2012).

Types of Food Quality Standards: How?

In the context of international food trade as well as the domestic level, a clear delineation of the goal of a regulatory regime, third-party certification system, or voluntary standard greatly facilitates discussion and analysis. Here, too, there is no definitive list or approach. The most common food quality regulatory regimes are those that focus on process and product performance standards. Further distinctions include input or ingredient standards and information requirements (see Van Camp et al. 2010, for an example of the US National Organic Program). A range of quasi-voluntary approaches have emerged from incentive or market-based, co-regulation, information/education, and industry self-regulation (Caswell

2012). Following the product through to the consumer, food quality standards may also target conditions of distribution and sale (e.g., temperature of refrigerated display cabinets) or services at the point of sale and conditions of use (e.g., nutrition disclosure at point of sale for food service operations). As requirements are implemented closer to the consumer, the potential for multiple international food quality standards to play a role greatly increases. For example, European grocers were concerned about the production environment for fruit and vegetables which are often imported. Efforts to document food safety, value, and production attributes throughout supply chains led to the development of traceability and certification systems based on Good Agricultural Practices.

Focusing on the international context of the management or regulatory rapprochement of differences between national-level mandatory controls leads to two major questions. The first is the legitimacy. In other words, does the national government have a valid reason to regulate a particular food quality attribute, and if so, is the regulatory regime it has chosen appropriate for achieving this goal? Under several trade agreements, the food quality standards set by international bodies (e.g., Codex) are the benchmarks (Hooker 1999; Hooker and Caswell 1999). The second question is how differences in regulation are managed to facilitate trade:

Harmonization: standardization of regulations in identical form

Mutual recognition: acceptance of regulatory diversity as meeting common goals (sometimes called reciprocity or equivalency)

Coordination: gradual narrowing of relevant differences between regulatory systems, often based on voluntary international codes of practice (sometimes called alignment)

The continuum begins with no regulatory rapprochement and moves to coordination, which is a broad range of weak forms of cooperation; then to mutual recognition; and finally to the strongest level of rapprochement, harmonization. Harmonization has most often been applied via minimum

input, process, or product performance standards for particular sets of food quality attributes. It can be applied across the full attribute space for these products. Mutual recognition involves agreement among a group of countries that a good legally produced within the bloc will be legal for sale throughout the bloc regardless of whether it meets the host country's domestic standards. It has most often been applied to value attributes because countries frequently do not like to give up control over food safety attributes in particular, although it may be applied across the attribute space. Coordination covers a wide variety of efforts to align policy through interagency consultations, adoption of voluntary standards, the provision of information through supply chains in traceability systems, and other means. It too may be applied across the attribute space. A total lack of rapprochement is possible, but increasingly rare as international food quality standards take on growing importance for all countries.

Quasi-voluntary standards include those managed by government agencies (such as the National Organic Program in the USA), supranational groups (such as ISO), NGOs, or businesses. They are characterized as necessary conditions to be a member of a particular supply chain, often involve experience or credence quality uncertainty and information asymmetry, but are more structured than voluntary international food quality standards.

Private certification programs, such as the Global Food Safety Initiative (GFSI), add another layer to the picture of international food quality standards worldwide. Such systems can be voluntarily adopted as a source of viable third-party certification that may back up or even replace government regulation of some quality attributes, most frequently value and production attributes. Increasingly, food safety attributes are being integrated within broader meta-standards (see, for example, Souza Monteiro and Hooker 2012, for an introduction to the role of third-party audits in the *Food Safety Modernization Act* in the USA). They are also playing an increasingly important role in contractual agreements, with many food processors and retailers requiring certification for all of their input suppliers. If these trends

continue, they will soon evolve into quasi-voluntary international food quality standards.

Summary: So What?

International food quality standards play a critical role in facilitating agricultural and food trade. Standards can be narrow or broad; are designed and managed by government agencies, third-party certification organizations, or business; are intended to minimize or mitigate search, experience, or credence information asymmetry and uncertainty; and focus on product or process attributes and/or information. Ideally standards continue to evolve in response to a diverse and dynamic set of stakeholder beliefs and needs. Concerns remain that despite efforts to enhance regulatory rapprochement, certain international food quality standards are used to impede trade and provide protection to domestic industry. This blocks the benefits of freer agricultural and food trade, creating ethical dilemmas.

Internationalization of Animal Welfare Standards

Michelle Sinclair

Centre for Animal Welfare and Ethics, School of Veterinary Sciences, The University of Queensland, Gatton, QLD, Australia

Introduction

Thanks to human progress, there is little doubt that the Earth is a much smaller place than previously. Technological advances in communication and travel have enabled enterprises and ideas to permeate previously inaccessible areas, in an increasingly globalized landscape. International trade is at an all-time high, including trade of animal products and live animals. This globalization has resulted in nonhuman animals being subjected to situations in which their welfare is severely compromised such as live-trade export and substandard transnational slaughter procedures. Conversely, globalization can be used as a gateway to also propagate social progression in the form of improved animal welfare standard implementation. Just as globalization is now allowing business ventures international opportunities, social progression issues now also have international exposure. This presents opportunities to move forward as a global community, which is less defined by borders. The question is how can this progress be achieved while avoiding the unfavorable (historically often “Western” led) impositions on culture, belief, and tradition that seem to counteract local engagement? Lack of local engagement dooms many international social initiatives to failure. The answer is multifaceted but can be generally described by three underlying concepts: *understanding*, *respectful nonjudgment*, and *empowerment*.

Understanding

In marketing, it is well understood that understanding your audience is key to success. The “not-for-profit” (NFP) sector is still coming to terms with this notion. The steadily growing availability of cross-cultural animal welfare research

has highlighted strong correlations between attitudes to animal welfare and nationality/sociopolitical region, more so than any other measured demographics including religion and ethnicity (Meng et al. 2009; Phillips and McCulloch 2005; Izmirli and Phillips 2011; Phillips et al. 2012; Sinclair and Phillips 2016). The only exception to this is gender, which is strongly associated with attitudes to animal welfare (Phillips et al. 2010). According to the theory of planned behavior, attitudes form the basis of behavior (Ajzen 1991), supporting the importance of understanding attitudes, within nation and region, when developing animal welfare initiatives and attempting to increase adoption of animal welfare standards. Anthrozoologists and their continued research are available to provide assistance in understanding the relationship between humans and nonhuman animals including the attitudes toward nonhuman animals and animal-related issues.

Respectful Nonjudgment

Respect and nonjudgment of culture, practice, and tradition seem to be obvious key components to ensure success of international initiatives but historically have often been overlooked, resulting in initiative failures and resistance to future initiatives. Respect and nonjudgment of culture, practice, and tradition include a genuine openness to approach the issue in a cooperative and solution-focused way, in addition to avoiding obviously inappropriate discriminatory, racist, or elitist behavior. Wildlife SOS India staged a highly successful campaign against the practice of dancing bears in 2014, by nonjudgmentally investigating the reasons for engaging in the practice and allowing their findings to inform campaign development. It was discovered that the motivation for using dancing bears was purely a requirement to economically provide for their families and that the people involved in this practice commonly felt resentment and distaste for their perceived requirement to dance bears to survive. Using this knowledge, Wildlife SOS developed a program that rewarded individuals for handing over their bear to designated sanctuaries by educating them in a new trade. By respectfully collaborating with their target audience in a nonjudgmental and

supportive way, the Wildlife SOS teams were able to work with the government to end the practice of dancing bears in India (Wildlife SOS 2009). If the team had approached the Kalandar people that were dancing bears in a judgmental and imperialistic way (e.g., by asserting “this is wrong,” “you are bad,” or “we know better”), it is doubtful that the same level of cooperation and outcome could have been achieved.

Empowerment

Lastly, and arguably most importantly when considering uptake of animal welfare standards, is the concept of empowerment. Empowerment begins with engagement, which begins by consulting with locals or the target audience at the outset. The purpose of this is to start with the mutual understanding that the local people know best what has been done, is being done, and importantly *can* be done in the future to achieve the desired outcomes. Local change, led by empowered local people, who are being supported to take the lead, has been a model for success within international projects in the past. One such example can be seen in the Bohol rabies elimination program run by Global Alliance for Rabies Control (GARC) in 2013, in response to a fatal rabies breakout on the island. Strategically chosen project leaders within the community were recruited, were educated about rabies and the methods of transmission and management, and were supported to implement measures that they knew the community would support. These included primary school education programs and community vaccination events. In a remarkably rapid time frame, 10 years ahead of their own forecasted dates, the island transitioned from unsuccessfully attempting to manage rabies by indiscriminately killing dogs in inhumane ways to a managed situation with rabies in check, creating a safer home for humans and canines alike (Lapiz et al. 2012). It is likely that if this initiative had been directed and led by an international team, the community engagement with the project would have been much less successful. An engaged and empowered group of people, who are in a position to change their environment, can achieve powerful and almost limitless

accomplishments. Successfully engaging and empowering teams of local people has long been accepted as an excellent way to ensure uptake of missions and strategic plans within the business management sphere, and it is a key indicator by which business climates are assessed in annual personnel surveys. However, NFP initiatives often miss this key element, opting rather for authoritarian-style programs that instruct people to change and outline how it must happen, often to the detriment of the program or message.

The rest of this article will briefly discuss animal welfare in a global setting, including why now is the right time for intentional animal welfare standards and improvements. The OIE international animal welfare standards will then be introduced, and a case study of one project raising awareness of these standards internationally will be presented.

Animal Welfare in the Global Landscape

Concern about the welfare of animals appears to be steadily gaining popularity and increasing in exposure the world over, although the degree varies by country. Festivals such as Yulin in Guangxi, China, have elicited large-scale international attention and condemnation for the inhumane treatment of dogs during slaughter. The same has occurred following incidences of large game trophy hunting in Africa, particularly if the hunted animal is perceived to have suffered. New global connectors such as social media, in particular Facebook, enable global social conversations, viral campaigns, and mass mobilization. These have been key in shining a light on concern for international animal welfare issues in a way that has never before been possible. Social media has been powerful enough to permanently impact the sociopolitical landscapes of entire countries, for example, as was seen during the “Arab Spring” political uprisings starting in 2010. New animal welfare legislation is being introduced in nations where it has not previously existed, such as in Thailand where the first animal welfare legislation was introduced in November 2014. Some nations are in the process of developing their first

animal protection legislation (such as China), and other nations are consistently improving pre-existing legislation based on the ever-increasing knowledge base of the nonhuman animal experience. In response to increasing concern for animal welfare within the worldwide community and a consumer desire for higher welfare products in areas such as Europe, major multinational companies are implementing improved welfare policies and practices. As a direct follow-on, these policies are mandated by their cross-border suppliers in nations such as China. Nestle, for example, announced a new science-based focus and dedication to the welfare of animals in July 2014, with the help of World Animal Protection and under the guidance of the World Organisation for Animal Health (OIE). These reforms commit to eliminating some of the most contested animal production practices with negative animal welfare implications, such as barren battery cages and “fast-growing procedures” for poultry, dehorning and castrating without anesthetic in cattle, and tail docking and gestation crates for pigs. The company has stated that its overall aim is to “remove the worst, promote the best, improve the rest” (Nestle 2014). This mandate flows through supply chain partners in 90 countries around the world and applies pressure on other major international companies to follow suit. Increasing export and import trading are also opening lines of communication between countries with more developed animal welfare legislative policies and requirements and those with an entire absence of animal protection legislation who have previously commonly engaged in practices that are scientifically proven to cause great pain and suffering. Within this multidimensional landscape of legislation, multinational commerce, growing body of science, and growing awareness and concern, the time is right for collaborative international animal welfare projects and standards.

World Organisation for Animal Health (OIE) Animal Welfare Guidelines

In the globalization and internationalization of animal welfare standards, the existence of

rigorously constructed and applicable standards is imperative. Such standards can be found in the World Organisation for Animal Health’s “Terrestrial Animal Welfare, Section 7 Animal Welfare,” and “Aquatic Animal Code, Section 7 Animal Welfare” (Office International des Epizooties 2014). The Office International des Epizooties (OIE), translated in English as the World Organisation for Animal Health (hereforth referred to as the OIE), is the intergovernmental organization responsible for improving animal health worldwide. OIE is a reference organization for the World Trade Organization (WTO) and so far has 180 member countries (member states) with regional and subregional offices on every continent (Office International des Epizooties 2015). At the request of the member states, OIE have developed animal welfare standards for slaughter and transport of terrestrial and aquatic animals, killing of animals for disease control, animal production systems, use of animals in research and education, and stray dog population control. The OIE acknowledges the challenges of implementing animal welfare standards in a multicultural world, where the perception of animal welfare including what constitutes cruelty differs greatly. The OIE states that “the scientific basis of OIE animal welfare standards provides the foundation for creating a consensus among all OIE Member Countries to support their adoption.” Consequently all OIE policies are based on rigorous scientific findings and are continuously evolving as our knowledge of animal welfare science evolves. The OIE codes, along with a multitude of additional animal welfare information provided by the OIE, can be found most readily on their website www.oie.int or in print form which can be ordered from the same place.

“Animal Welfare Standards” Project

According to the OIE, “the establishment of standards is one challenge; however, the implementation of the standards is even more difficult” (Kahn and Varas 2013). Many of the OIE member countries host industries that are not aware of the OIE standards or where to find them and often

resulting in a failure to adhere to the standards despite the OIE member countries being mandated to take the lead on global animal welfare standards. Reasons for this failure to adhere to the standards could include a lack of perceived ability to follow and apply the standards because of a lack of relevant knowledge and skills or a failure to see the benefit in changing procedures. The OIE New Zealand and Australian Collaborating Centre for Animal Welfare Science and Bioethical Analysis has spent the last 2 years teaming up with Universiti Putra Malaysia (UPM) in a project led by the Centre for Animal Welfare and Ethics of the University of Queensland in Australia to improve the knowledge of and adherence to the OIE standards. This project supports the OIE Regional Animal Welfare Strategy for Southeast Asia's vision of "a region where the welfare of animals is respected, promoted and incrementally advanced, simultaneously with the pursuit of progress and socioeconomic development." The objectives within this project are threefold: (1) to enhance knowledge of OIE slaughter and transportation standards in Southeast and East Asia, (2) to provide training for key personnel involved in transport and slaughter practices in Southeast and East Asia, and (3) to conduct research to determine attitudes to slaughter and transport among key stakeholders and interested parties in the region and to determine the current motivations and barriers to improve welfare practices (The New Zealand and Australia OIE Collaborating Centre for Animal Welfare Science and Bioethical Analysis 2016). The project team developed a top 10 of basic messages for improving welfare during transport and at slaughter, derived from the OIE Terrestrial Animal Health Code and developed in consultation with local coordinators in each country. Next, workshops were held to "train the facilitators" (mainly government veterinarians and senior university lecturers) in each of the collaborating countries: Malaysia, China, Thailand, and Vietnam. These facilitators, in turn, have so far trained over 800 relevant industry stakeholders such as slaughterhouse managers and industry inspection officers. The attendees from each country had different focuses in animal welfare and different

interests and challenges. However, some factors were common to all countries including the challenge of governmental monitoring and enforcing of animal welfare standards and the vast difference in standards between large, often government-run, slaughterhouses and the smaller locally run slaughter operations. Data collected during this project on the perceived barriers and motivators in embracing and facilitating improvement in animal welfare during slaughter and transportation is due to be published in 2016 (Sinclair et al. 2016). The purpose of this research is to attain more locally based information that will enable more specific tailoring of animal welfare-based projects in each region in the future in order to improve project engagement and success. Resources about the OIE standards were specially created to support the project activities. These resources were translated into local languages and are freely available via the project website: www.animalwelfarestandards.org. This project has been a successful example of international collaboration to raise awareness about the international OIE animal welfare standards and capacity building to empower adherence to the standards and ultimately improve animal welfare.

Conclusion

If current trends persist, animal welfare will continue to grow as a field in science, as an important component of agribusiness, and as a focus for not-for-profit organizations. To move forward with international animal welfare initiatives, focusing on four key basic principles could be useful: (1) use and raise awareness of the pre-existing OIE international standards; (2) continue researching the sociopolitical and regional audiences with respect, understanding, and lack of judgment prior to attempting to implement projects; (3) prioritize collaboration and engagement by empowering locally led initiatives; and (4), where possible, build programs into the initiatives which can also improve the welfare of the local community and stakeholders. The last is of particular importance within developing nations and is often overlooked. Although research continues in

the area of factors that motivate people to improve animal welfare, attitudes to animal welfare are arguably tied to economic development. Despite this, vast progress can be made and has been made in improving animal welfare, largely due to careful research, consultation, and considering of impacts to human welfare in addition to non-human animal welfare.

In general, the current global export and legislative landscape, coupled with the successful work conducted across the globe by international organizations (e.g., World Animal Protection, OIE, Food and Agriculture Organization of the United Nations (FAO), and the multitude of domestic animal advocacy teams), draws attention to a great opportunity for continued success in improving the welfare of animals around the world. The receptiveness of stakeholders and target audiences to well-run engaging initiatives means more opportunity for international animal welfare projects and greater adoption of international animal welfare standards into the future.

Islamic landscapes for food practice; Muslim identity through food practice

Introduction

An exploration of food and Islam must begin with food's role in the Qur'ān, Islam's holy book. For Muslims, this book is the record of divine revelations made to the Prophet Muhammad, intended to guide humanity. The Qur'ān describes how food originates, what it signifies, and what foods are allowable or prohibited, which inform Muslim identities and Islamic theology, law, ethics, and aesthetics. In addition, Muslim food practices follow from traditional stories (*ḥadīth*) about the Prophet Muhammad and his companions. Islamic legal prescriptions not only identify what foods are religiously sanctioned for Muslims but also the manner of their preparation. After discussing what Muslims are prescribed to do with respect to food, this entry examines practices observed around the world, which show the importance and incorporation of food for ritual occasions,

holy festivities, and commemorations. Finally, the entry briefly considers animal rights and vegetarianism, agricultural sustainability and the issues brought about by food industrialization and globalization, and the scriptural connection of food with paradise.

Food as Blessing and Reward

Let people consider their food: We [God] pour down water abundantly and cause the soil to split open. We cause grain to grow out of it, and vines, edible plants, olive trees, date palms, gardens dense with foliage, fruits and herbage, all for you and for your livestock to enjoy. (Qur'ān 80:25–32)

Drawn from the Qur'ān, the epigraph above depicts food as a divine blessing for humans and livestock to enjoy. The provisions that God has set on earth are an indication of God's wisdom, reminding adherents that God is without equal, incomparably wise, and generous (Q. 2:22). Food makes its appearance in paradise (*al-jannat*), in which the original couple, Adam and his wife, are directed to enjoy food from the plenteous garden wherever they find it, but not to approach a certain tree, lest they become tyrannical or wrongdoers (*ẓālimīn*) (Q. 2:35). They partake of it nonetheless and are thus banished from the garden, after being forgiven and counseled to follow God's guidance (Q. 2:38). Sometimes human beings are tested by hunger, loss, or meager harvest, but those who respond with patience and assert that they are from God, to whom they will return, are divinely blessed (Q. 2:155–157). God provides succor when asked, as when Moses prayed for water for his people and was directed to strike a stone with his staff, at which instant 12 springs appeared (Q. 2:60), as a reminder to live a life of righteousness. Believers who do righteous deeds will secure a place in paradise, where waters flow and gardens grow and where they will be offered fruit (Q. 2:25).

Lawful and Prohibited Foods

The theme of not approaching, that is, not partaking of the fruit from a certain tree, continues in the

Qur'ān in Chap. 5, appropriately titled "The Table Spread" (*al-mā'idah*). This entry identifies foods (*ṭa'ām*) that are prohibited (*ḥarām*) and foods that are permitted (*ḥalāl*). The list of *ḥalāl* or "lawful" foods includes grazing livestock (Q. 5:1) and animals hunted while not in a state of *iḥrām* (the state observed during the time of pilgrimage (*ḥajj*), whether minor (*umrah*) or major (*ḥajj*), during which a pilgrim performs rituals of purification and wears prescribed clothing) (Q. 5:2 and 22:29). In addition, "the food of those who were given the Scripture" (Q. 5:5) is permitted, as is the food of the Muslim permitted to other scripturists, usually interpreted as Christians and Jews. Prohibited or *ḥarām* foods include blood, dead animals (*maytah*), the flesh of swine, animals offered in sacrifice to other than God, or animals that have been gored and killed through strangulation or a violent blow or remnants from what wild animals have eaten. However, God gives mercy and forgiveness to a person who partakes of any of these without the intention to sin due to severe hunger (Q. 5:3; see also 2:173, 6:145, and 16:115). Consequently, due to the emphasis on the manner of an animal's killing, Islamic law requires that animals be killed in a prescribed way, such that its blood drains out. Q. 6:118–121 further specifies, "And eat of that [meat or food] over which the name of God has been mentioned. . . and do not eat from that over which the name of God has not been mentioned, for indeed, it is grave disobedience." Wine (or more accurately, intoxicants, *al-khamr*) is also forbidden (Q. 5:90). Although specific interpretations may vary (below), most scholars agree that alcohol, pork, blood, and carrion meat are prohibited.

Islamic Legal Prescriptions

The Qur'ān provides compelling passages about food, and Islamic legal scholars engage with food and eating with attention to *sharī'ah*, the term for Islamic legislation, which literally means the path to the watering hole. Thus, jurists present Islamic law as a means for quenching the thirst for divine order and justice. Daily activities, such as prayer

and charitable acts, show piety and submission to God's laws, as does the food one partakes of daily. Islamic law concentrates considerable attention on food, particularly defining what is lawful (*ḥalāl*) and prohibited (*ḥarām*). The term *tayyib* is useful for describing good and wholesome food. In addition, the Prophet Muhammad is considered the exemplar of correct behavior in accordance with the belief that as God's Prophet, he was divinely guided. The Prophet's words and actions are paradigmatic, as are those of his closest companions. Such exemplars are recorded in a body of literature known as the *ḥadīth* or traditions. When scholars describe Muhammad's fasting or his meals, these *ḥadīth* stories offer prime examples for Muslims to emulate. For example, the Prophet was known to wash his hands before a meal and to break his fast with dates. Food is among the characteristics defining a Muslim in a *ḥadīth* ascribed to Muḥammad, in which he said, "Whoever recites our prayers and worships in the direction of our *qiblah* [facing the Ka'ba, the sanctuary in Makkah (Mecca)] and eats the meat of our slaughtered animals, that person is a Muslim who has the protection of God and the protection of His Messenger" (*Ṣaḥīḥ al-Bukhārī*, 1:82–83, cited in Freidenreich, 144).

The Arabic term *ḥalāl* is broader in scope than simply describing food restrictions. *Ḥalāl* refers to what is lawful or permissible, more generally, in contrast to *ḥarām*, the unlawful. In Islam, any action may be placed within one of five legal-ethical categories: *ḥarām* (forbidden), *makrūh* (reprehensible), *mubāḥ* (neutral or indifferent), *mandūb* or *mustaḥabb* (recommended or commendable), and *wājib* or *farḍ* (required). Islamic law regulates meat more carefully than other foods. These laws deal with the raising and slaughter of food animals, and many authors highlight the humane treatment of animals exhibited in the Qur'ān on account of creatures constituting communities, as do humans (Q. 6:38). Q. 5:3's reference to "a proper act of slaughter" entails that God must be invoked and, to avoid prolonged suffering, a carotid artery and the trachea must be cut with a sharp knife. There is a specific way of naming God for animal slaughter, first stating intent (*niyyah*) to begin the ritual act of slaughter,

followed by invoking God according to this formula: “In the Name of God, God is most Great,” in Arabic “*Bismillah, Allahu akbar*.” Meat prepared from an animal thus slaughtered is known as *dhabīḥah*. Both the Torah and the New Testament prohibit eating blood, a prohibition that is also found in the Qur’ān and links the Muslim community to the shared divine covenant with the peoples of the Book (commonly understood to be Jews and Christians). The blood of the slaughtered animal is allowed to drain before the meat is prepared for consumption.

Halāl and *ḥarām* foods are elaborated in multiple schools of Islamic law, which are based on the Qur’ān but also draw heavily on the *sunnah*, both oral and written record of the practice of the Prophet Muḥammad and his close companions. Thus, al-Ṭabarī (d. 923) permits the meat of slaughtered animals prepared by the peoples of the Book (Jews and Christians), but not that prepared by polytheists and worshippers of images and statues. The Sunni and the Shi’i jurists, both of whom commonly appeal to the Qur’ān but otherwise appeal to different sources of authority, differ in their views on whose meat is permissible to Muslims. Sunni jurists such as Ya’qūb Abū Yūsuf (d. 798) also forbid eating the meat, but not other foods, of Zoroastrians (Magians), even though they are otherwise in all respects to be treated as peoples of the Book, as it entails the act of ritual slaughter in which the animal is offered to many deities. Ibrāhīm al-Nakhā’ī held that eating meat over which a Christian butcher had invoked Christ was reprehensible. However, even though ostensibly Christians invoke Christ, rather than God, when slaughtering animals for food, Sunni jurists such as Abū Bakr Muḥammad Ibn al-‘Arabī (d. 1148; not to be confused with Muḥyi al-Dīn, the famous Ṣūfī) calls upon God’s making permissible meat prepared by the peoples of the Book sufficient divine generosity to justify eating their meat, despite their Qur’ānically unacceptable elision of Christ with God. Ibn Hazm in his chapter on animal slaughter ruled that Zoroastrians were to be treated as peoples of the Book, implying that all foods prepared by them were allowable. In contrast, Shi’i jurists such as Muḥammad b. al-Ḥasan al-Ṭūsī (d. 1066/7)

allowed for grain and other foodstuffs prepared by non-Muslims, but not meat slaughtered by them. This prohibition occurred despite the concession granted to peoples of the Book by Q. 5:5 and despite the permission, provided the name of God had been recited over the animal slaughter, granted by Zayd b. ‘Alī (d. 740), whose lineage traced directly back to ‘Alī, the first Imām of the Shi’ah (and hence considered by the Shi’ah to have inherited the Prophet’s spiritual and temporal authority). Interestingly, the authority of the sixth Imām (sixth for Ithnā ‘Asharī or Imāmī Shi’ites; the fifth for Fāṭimīd Shi’ites), Ja’far, is invoked to argue opposing positions. On the one hand, his authority is invoked to suggest that only the name of God invoked by monotheists, understood by those who interpret the text restrictively as Muslims, can be trusted. On the other hand, his authority is cited to suggest that meat prepared by any butcher who invokes God’s name properly, irrespective of faith, is permissible to eat, invoked by Fāṭimīd Shi’ites also. Thus, for some Muslims, all foodstuffs with the exception of grains and the like (i.e., unprocessed foods) are rendered impure (*najis*) for consumption when prepared by non-Muslims. The goal here is to distinguish Imāmī Shi’is from Sunnis in the latter’s acceptance of foods from scripturalists. Such food restrictions are deployed as a strategy to draw a line in the sand separating Imāmī Shi’is from all other faith communities. Dietary restrictions established by religious groups as a mode of distinguishing self from other are visible in non-Muslim religious settings, as well. Clearly, such distinctions both within the Qur’ān and outside it have much to do with setting the terms on relations with other religious communities as a mode of self-identification. Among Muslims, these prohibitions extend from the idea that unbelief and impurity – exemplified through the holding of false beliefs – can be communicated through touch.

Feasting and Fasting: Food and Ritual Occasions

Feasting and fasting are both religious prescriptions that mark ritual commemorative occasions,

which remind adherents about their sacred history. Feasts and fasts are junctures at which one may reflect upon and strengthen one's faith. While designated times of feasting are usually joyous occasions, they sometimes follow periods of privation, often expressed through fasting, that allow for introspection, prayer, heightened moral reflection, and charity and goodwill toward others.

Ramadan

One of the *arkān* or pillars of Islam is fasting (*ṣawm*) during the Islamic month of Ramadan, prescribed in Q. 2:183–185. In the lunar calendar, Ramadan is a month when Muslims practice fasting from dawn (*fajr*) to dusk (*maghrib*) to strengthen their religious commitments. Due to the difference between the lunar and solar calendars, the month of Ramadan shifts each solar year, slowly transitioning from one season to another. The fast consists of refraining from food, drink, and intercourse during daylight hours, breaking the fast (*iftār*) each evening after dusk and beginning the day before dawn with a small meal (*suhūr*). The predawn morning meal is generally lighter, since some believe a heavy meal will inspire more thirst during the day's fast. Just as the pilgrimage to Mecca (*hajj*) is both an outer and inner journey to God's abode, the fast at Ramadan serves inner and outer functions. The Ramadan fast involves the physical discomfort of hunger and thirst, which encourages self-restraint, compassion toward those who live with daily hunger or want, and gratitude for having sustenance. It also entails cultivation and control of the mind, beginning with expressing the *niyyah* or intention to fast, restraining oneself from coarse speech and quarrelsomeness, avoiding lustful and avaricious thoughts, and encouraging an attitude of benevolence toward others, often through acts or gifts of charity. Remaining steadfast in God's requirements despite discomfort may be purifying to the mind and body. This is also a time for each fasting Muslim to spend in prayer and meditation, renewing faith, increasing moral self-awareness, and considering his or her life purpose. When people are unable to complete their fast during Ramadan due to temporary illness or travel, the fast may be completed later. If fasting presents

extreme difficulty, a Muslim may compensate by feeding someone in need (Qur'ān 2:184). Pregnant women and young children are exempt from fasting. Also Muslims tend to visit their place of worship more frequently.

During the month of Ramadan, fasting Muslims eat after darkness falls before performing the sunset prayer (*ṣalāt al-maghrib*). The daily fast closes after sunset with dates or fresh fruit, followed by *iftār*, the evening meal after the day of fasting. Eating dates is associated with the Prophet Muhammad, who reportedly loved dates and broke his fast with dates and water. Because Ramadan is the most significant time of year in Islam, the Prophet's practices become more important for expressing religious commitment. Camel meat is another food associated with the Prophet and his family and thus eaten more frequently in Ramadan evening meals. Many *iftār* dishes vary regionally, depending on local food preferences and lore regarding which foods and drinks are best for delighting the palate, strengthening the body, and quenching thirst. *Rooh Afza*, for instance, is a nonalcoholic drink concocted by Hakeem Hafiz Abdul Majeed in 1906 in India, consisting of a medley of herbs, fruits, vegetables, flowers, and roots, that is now sold as a syrup to be added to water, ice cubes, sugar, milk, and cinnamon and prepared in India and Pakistan as a drink to be served during *iftār*. Indonesians prepare desserts such as *kolak*, made with palm sugar, coconut milk, pandanus leaf, mung beans, and fruit, to which optionally tapioca or cassava may be added, cooked, cooled, and served during the month of Ramadan. *Lāghmān* noodles, derived from *lamian*, a type of Chinese noodle, are favored as *iftār* dishes in Central Asia and Chitral, while in places such as Trinidad and Tobago, local fare such as roti with curried chicken, goat, duck, and chickpeas is served at the masjid or mosque as part of a communal *iftār* meal. Russian Muslims drink *kvass*, whose low alcohol content classifies it as a nonalcoholic beverage. *Kvass* is made from fermented rye bread and mixed with fruits and/or mint as it is thought to staunch thirst.

The month of fasting ends with a celebration held on the first of the following month, Shawwāl, the 'Īd al-Fiṭr (festival of breaking the fast), in a

show of gratitude. Fasting is not permitted on this day, which begins with a small breakfast that often includes dates before the performance of special prayers, sermons exhorting good deeds, new clothing, and family meal gatherings. Countries such as Egypt declare the occasion fit for a 3-day holiday to allow families restorative time to gather, share meals, and celebrate.

ʿĪd al-ʿAḍḥā

This feast day or *ʿīd* (Eid), occurring on the 10th of the Muslim lunar month Dhū al-Ḥijja, commemorates the Prophet ʿIbrāhīm's (Abraham) willingness to sacrifice his son Ismāʿīl (Ishmael) and marks the end of the annual *ḥajj* or pilgrimage to Makkah (Mecca). It is a time when special Eid prayers are recited, new clothes are worn, and gifts are given, especially to children. Families and friends gather for a meal usually consisting of an animal that has met certain age and quality standards, who has been ritually slaughtered for the occasion, to mark the replacement of Ismāʿīl with a ram as he was about to be sacrificed. Pilgrims participating in the pilgrimage make this sacrifice in the valley of Mina. At least two-thirds of the animal is to be shared with the community, one-third is retained by the family, one-third given to extended family and friends, and one-third given in charity so that no one is left without the means to commemorate this occasion.

The Saudi Project for Utilization of Hajj Meat (www.adahi.org) reports close to a million heads of sheep, and 3000 heads of camels and cows were utilized during the 2011 *ḥajj* season. The Kingdom of Saudi Arabia established this organization, which now employs close to 40,000 people, approximately 20 years ago to serve several functions: to distribute meat to the poor in Makkah, as well as to needy Muslims around the world; to ensure the fulfillment of religious and health regulations for animals; to ensure environmental protection around the holy sites of pilgrimage; and to distribute the proceeds from the sale of offal to the poor in Makkah. A map shows recipients of meat ranging from places in West Africa to the Sudan, Mozambique, and Tanzania to regions further east in Azerbaijan, Pakistan, and Bangladesh. The organization's stated objectives

reflect some awareness of the environmental costs of the ritual practice of slaughtering animals for Eid in asserting that no such meat should be wasted. However, animal rights organizations such as Animals Australia (www.animalsaustralia.org) protest the exportation of live animals to Muslim-majority countries such as Turkey, Indonesia, Kuwait, Egypt, and Pakistan on the grounds that the animals are treated cruelly and as part of their larger campaign to stop animal exportation and to encourage people to adopt vegetarianism to reduce the water and other resources needed to raise livestock. Increasingly, Muslims themselves are asking whether the custom of commemorating the Eid continues to justify the scope and scale of the practice, on moral and environmental grounds; however, serious debate and reflection have yet to be undertaken. The Saudi Project for the Utilization of Meat announces the message of the project on its website thus:

"Exhort all men to make pilgrimage. They will come to you on foot and the backs of swift camels from every distant quarter (Q. 22:27); they will come to avail themselves of many benefits to pronounce on the appointed days the name of Allah over the cattle, which He has given them for food." "Eat of their flesh, and feed the poor and the unfortunate." (Q. 22:28, 36) "Their flesh and blood does not reach Allah; it is your piety that reaches him." (Q. 22:37)

Is it possible to theologize constructively about animal sacrifice at the time of pilgrimage bearing in mind the tremendous moral and environmental costs of observing a ritual whose scale has gone far beyond that at the time the Qurʾān was revealed? While these verses proclaim that pilgrims are to offer animals in sacrifice, they do not require that Muslims not on pilgrimage do so as well, while the final verse invoked here opens up the possibility that the animal sacrifice could be offered symbolically, since God is the recipient of piety and not the flesh and the blood of the animal.

Muḥarrām Rites

The first month of the lunar year is Muḥarrām, considered by early Muslims to be one of the sacred months during which no blood could be shed, including the hunting of animals. The 10th of Muḥarrām is called ʿĀshūrāʾ, and the traditions

(*ḥadīth*) relate that upon being told that the Jews fast on this day to commemorate the day when God parted the Red Sea to let Moses and his people pass in order to rescue them from the Pharaoh, the Prophet told his people to fast for 2 days, on either the 9th and 10th of Muḥarram or the 10th and 11th. This fast is considered recommended, not obligatory, by Sunni Muslims, having been replaced by Ramadan as the obligatory period of fasting. Fasting Muslims in Egypt will prepare a pudding called Ashura made from wheat, nuts, raisins, and rosewater to be had after dinner on that day.

For Shi'ah Muslims, the month of Muḥarram is a time of intense sadness and mourning. On October 10, 680 CE (10th of Muḥarram, 61 AH; anno hijri (AH) marks the commencement of the Muslim lunar calendar dating from the flight or *hijra* of Muslims from Makkah to Madinah in 622 CE), the Prophet's grandson, Ḥusayn b. 'Alī, was massacred on the battlefield near Karbala (in present-day Iraq) by Ibn Ziyād, governor of Kufa, whose forces were allied with Yazīd I, the Umayyad caliph. Significant in this narrative is that Ḥusayn's small band of followers and family was cut off from access to water from the nearby Euphrates River. Ḥusayn's grave became a pilgrimage site. Shi'ite tradition holds that Ḥusayn's sister Zaynab began a period of mourning for her brother, which Shi'ites observe to this day in 'āzā dārī (mourning) rituals and gatherings (*majālis*) at which sermons are made recounting the events leading up to the massacre, elegies recited, prayers offered, and lamentations expressed, alongside processions during which participants, mostly men, will express their grief through *matam*, consisting of rhythmically striking their chests or their backs with chains or with small sharp blades. The Shi'ite period of mourning, commencing with the sighting of the crescent moon announcing the first of Muḥarram (the Islamic calendar counts its days from sunset rather than sunrise), lasts to the fortieth day (*Chehellum*) after the 10th of Muḥarram, and during this period of mourning, joyous occasions such as weddings and birthdays are not observed.

In Karbala-related mourning rituals in South Asia, meat is avoided during the Muḥarram month

because of its association with times of celebration and joy; most Shi'is observe the tenth of Muḥarram not as a fast, a *roza*, connoting auspiciousness, but as a day of *faqā*, poverty and hunger, in emulation of and solidarity with Ḥusayn and his retinue's hunger and thirst in the 3 days preceding their martyrdom. Tradition also holds the occasion of the massacre was utilized by Ibn Ziyād and his troops to denote a time of auspiciousness. Hyder writes: "The meal on the tenth of Muḥarram consists of *khichrī* (rice cooked with lentils), *khaṭṭa* (tamarind soup), and *butti* (yoghurt rice); butti, though a staple in many South Indian households, is eaten in most Shii Hyderabad households (sic) only during this Muharram meal." (Hyder 2006) Majlis attendees are given *tabarruk*, consecrated food, which varies from region to region depending on local cuisines. An ethnographic account from Karachi, Pakistan, notes that the distribution of food such as *halīm*, made of wheat, barley, lentils, and spices, with or without meat such as beef, mutton, or chicken, and water is held by many Shi'is to recompense for the oppressed who died while hungry and thirsty. *Sabils* (or stalls for the distribution of water by children to passersby) acknowledge the thirst of those on the battlefield who were cut off from water. Here, the breaking of the day of hunger and thirst, the 10th of Muḥarram, was observed with *halīm*, *roti* (a kind of round flatbread made with wheat flour), milk, and water (Schubel 1993).

Navrūz

The festival of Navrūz, "New Day," occurs at the spring or vernal equinox and marks the beginning of the Persian New Year. It has been celebrated from ancient times to the present in Persian civilization and is observed by Shi'ite communities influenced by Iranian culture as well as other faith communities in the Persianate world. The Achaemenid (559–330 BCE) and Sassanian (226–652 CE) kings celebrated the festival with public feasts and the giving of gifts, while the populace built fires and sprinkled water on each other. Among the customs observed by these pre-Islamic dynasties, the number seven figured prominently, and this ancient memory is still

preserved in contemporary Shi'ite celebrations of Navrūz in the *haft-sīn* laid out on the table. The *haft-sīn*, “seven [items beginning with the letter] ‘s’,” are *sabzeh*, wheat, barley, mung bean, or lentil sprouts specially sprouted for Navrūz, symbolizing rebirth; *samanū*, a wheat germ pudding symbolizing prosperity; *senjed*, dried silver berry or oleaster, symbolizing love; *sīr*, garlic, symbolizing medicine; *sīb*, apples, symbolizing health; *sumāq*, sumac, symbolizing sunrise; and *serkeh*, vinegar, symbolizing maturity and patience.

Navrūz marks new beginnings for both natural and spiritual worlds, just as springtime is essential for new growth, and divine revelation is essential for spiritual growth. This theme of renewal is expressed through growing sprouts from grains or lentils in small containers, and the resulting *sabzeh* is placed on the Navrūz table. Other offerings include decorated eggs, fresh fruit, baked goods, a mirror, a copy of the scripture observed by the household (in the case of Muslims, the Qur'ān), a bowl of water in which leaves and flowers are set afloat, and sweets. The Navrūz “season” lasts 12 days, and on the 13th day, the *sabzeh* is cast into a river to symbolize the flowing away of the previous year's troubles. Among some Shi'ite communities such as the Ismā'īlis, small packets of grain are handed out on Navrūz to denote blessings for the year (Kassam 2006).

Animal Rights and Muslim Vegetarians

The Qur'ān affords rights to animals, including livestock. Livestock have rights to water, pasture, and fair treatment (Foltz et al. 2003). Animals are recognized to live in communities, thus using an otherwise human category to show the value and respect animals deserve, including recognition of their relationships to each other (Foltz et al. 2003) (Q. 6:38). However, vegetarianism has remained unpopular, even receiving negative attention from major theological leaders. Nonetheless, certain poets and mystic-Sufi historical figures ate vegan or vegetarian diets. A tenth-century poet named al-Ma'arri who avoided eating meat was accused of “trying to be more compassionate than God” (Foltz 2006). This serious accusation is called

shirk, or sharing God's identity, comparing oneself or anything less than God with the unmatched, unique divinity of the one God. For contemporary Muslims in diaspora, the choice to eat vegetarian becomes important when faced with meat raised in an inhumane manner or with growing concerns about the environmental costs of raising livestock, in addition to traditional concerns discussed above regarding *halāl* and *dhabīhah* slaughtering methods.

Modernity, Western Cultures, Industrial Agriculture, and Globalized Food

In many Muslim societies, traditional techniques valuing flavor and quality have given way to some extent to the industrialized techniques found in Western nations emphasizing quantity and economic value. Like other modernizing influences, food transformations have included both enthusiastic emulation of a transnational, industrial cuisine, as well as return to and revival of perceived traditions and rejection of outside influence. Both sentiments underlie cultural commitments and elements between fantasies of modernizing improvements and nostalgic hopes for cultural continuity, as modernity itself can give rise to nostalgia. However, New World foods such as the tomato and contemporary techniques such as frying largely have been indigenized. Some scholars of Middle Eastern foodways argue that such transformations are inevitably political. For example, “food nationalism” uses foods and narratives of food origins in constructing national identity (Zubaida and Tapper 2011).

Since the 1970s, international fast food can be found in Muslim-majority regions, though these establishments ride the political tide of US popularity. Anti-Western and anti-American sentiment can be targeted at these chains; thus, branches may close when the United States or pro-American political groups ebb in political favor (Heine 2004). McDonald's fast food is exotic, more costly than local food, and tends to appeal to youth interested in modernity via Westernization (Heine 2004). On the other hand, *halāl* consumption has been on the rise among young Muslims

in France as a means of expressing identity (Bergeaud-Blackler 2006).

Meanwhile, the global *ḥalāl* market is burgeoning, becoming further mobilized and professionalized within international commodity trading and industrial business models. The international *ḥalāl* food market is sizable, but entrepreneurs have an eye to expanding its reach, rendering more of the world's approximately one billion Muslims into globally traded *ḥalāl* food consumers. *Ḥalāl* advertisements and educational materials appear on the Internet, some emphasizing social media connectivity, reflecting a highly technologized setting to market products in a global trade environment.

In global food production, genetically modified organisms (GMOs) are recent developments, thus without Qur'ānic precedent, but subject to contemporary legal interpretation or lack thereof. Some Muslims consider GMOs to be dubious, falling into either questionable or not permissible categories. Others have considered and approved use of GMOs, allowing anything not named *ḥarām* in the Qur'ān. The Islamic Jurisprudence Council decided that GMOs can be considered *ḥalāl*. Some scholars propose that if a GM animal or plant food derives from pork or other *ḥarām* (impermissible) foods, then the GMO will also be *ḥarām*. If not, then the GMO is acceptable. Ali Maarabouni reports that religious leaders considering GMOs emphasize human responsibility for nature's health (Maarabouni 2003). Reflecting appreciation for nature as God's gift, these leaders asserted that if GMOs damage nature, then they should be prohibited, thus rendering GMO food labeling relevant.

Against the background of GMOs and international trade in *ḥalāl* products, Muslim organizations have arisen to promote eating locally and humanely raised *ḥalāl* meat from farms with fair labor practices. In the United States, for example, the agricultural models utilized by Taqwa Eco-Food Cooperative (now Whole Earth Meats) in Chicago, Illinois, and Norwich Meadows Farm in Norwich, New York, provide an alternative to industrial agriculture, which is pesticide and technology intensive. Taqwa leaders envisioned their more traditional agricultural model to resemble

that found in the Prophet Muhammad's era, a contrast to the serious ethical challenges to animal welfare found in factory farms and the large-scale, commercial meat industry.

Ending in Paradise: "Perpetual Gardens Graced with Flowing Streams" (16:31)

In Islam, paradise is literally "the garden," a lush land gushing with streams of milk and honey. In this blissful garden, food and drink are rewards for good works and right living (Q. 16:30–32, 52:19). Food represents not only practical physical nourishment but also spiritual fulfillment. Not only food, but drink is plentiful in the forms of water, milk, honey, and wine, listed as gifts from God in addition to forgiveness (Q. 47:15). Wine is the only *ḥarām* item that appears in blessed abundance in paradise, though other passages name paradisiacal drink as nonintoxicating (Q. 52:23, 56:18–19). Interestingly, the well-watered paradise appears comparable to a well-managed garden subject to a sustainable land ethic, perpetually abundant.

In al-Bukhari's *Al-Adab Al-Mufrad*, a tradition (*ḥadīth*) of the Prophet Muhammad instructs people as they face the Final Day, "If the last day comes and you have a sprouting palm in your hand, plant it." Thus, agriculture remains religiously relevant even to the end of time.

Summary

Islamic food practices derive from the Qur'ān and *ḥadīth* traditions depicting the Prophet Muhammad and his close companions, who offered the best examples of how to live a morally righteous life with specific directions relating to food and animals. Multiple Qur'ān passages show the importance of food practices, delineating foods that are lawful (*ḥalāl*) or unlawful (*ḥarām*). Islamic legal scholars have interpreted specific text passages, which then influence food traditions in various Muslim communities. These communities can differ in legal interpretation, though alcohol, pork, blood, and carrion are commonly understood as unlawful. Feasts and fasts are central

occasions for expressing and reinforcing Muslim piety, particularly Ramadan, ʿĪd al-Fiṭr, ʿĪd al-ʿAḍḥā, Muḥarrām, and Navrūz. Though Muslim vegetarianism is uncommon, land and animal protection is encoded in Islamic scripture and law, if underutilized. Contemporarily, food's industrialization and globalization influence (1) the global *ḥalāl* food market, (2) fast food's social role in Muslim-majority regions, (3) the current Islamic legal conversation on genetically modified organisms (GMOs), and (4) religiously motivated movements in Western cityscapes that embrace sustainable, *ḥalāl* agriculture. Finally, the Qurʾān depicts paradise as a garden flowing with streams and abundant with fruit. This paradisiacal vision resembles the resplendent results of a well-managed land ethic, yet represents spiritual fulfillment and the rewards for moral living.

Islam and Food and Agricultural Ethics

Frederick Mathewson Denny

Department of Religious Studies, University of Colorado at Boulder, Boulder, CO, USA

Introduction

The Islamic religious tradition was founded in western central Arabia by the Prophet Muhammad in the seventh century CE, based on oral recitations that he received which he and his followers believed to be from Allah/God. Islam is an Arabic word meaning “submission,” in this context to Allah, whose recitations to Muhammad by means of the archangel Gabriel continued for some 22 years and were known as the “Qurʾān,” meaning divine “recitation.” Although the Prophet Muhammad was himself not literate (“able to read”), his followers eventually gathered the recitation chapters, known as Suras, into a canonical (“official, sacred”) text which has descended since the founding period as the principal resource for Muslims (those who have “submitted” to Allah) to understand and obey their branch of ethical monotheism preceded by Judaism and Christianity with all three tracing their lineages back to the Patriarch Abraham (see the biblical book of Genesis, beginning with Chap. 11, concerning his life and influence).

Although the Qur'an is the most authoritative source for Islamic doctrine, worship, and law, a second authoritative source was produced based on the Prophet Muhammad's life and teachings as the tradition's founding father. This source is known as the prophet's Sunna, meaning the "custom," "way of acting" of a person, particularly of the Prophet Muhammad in this context throughout his years of leadership of the early Muslim community in the Holy City of Mecca and later in the base of the developing Islamic government in the northern city of Medina, where Muhammad and his companions settled following their *hijra*, "emigration," in 622 CE. The Sunna of the Prophet Muhammad contains many individual "reports," "events," and "quotations," known in their original Arabic language as *hadīths*. While these reports do not have the status of divine revelation, which the Qur'an is believed by Muslims to be, they are nevertheless of central importance when they address subjects, situations, and detailed information about practicing Islam correctly but not contained in the Qur'anic text. And since the Qur'an does declare Muhammad to be Allah's "Messenger" (*rasūl*, e.g., in Sura 48:29), that means a great deal in how the developing Muslim community regarded him as a vital source of guidance.

In this entry on food and agricultural ethics in Muslim life and practice, it is important to understand that many of Islam's teachings and standards are based on the Qur'an, Islam's holy scripture, and the Prophet's Sunna as found in many *hadīth* reports from several influential collections that were shared and published over the first two centuries of Islam's development into a major tradition among the world's religions.

Food and Drinks Addressed in the Qur'an

Food and potable liquids (lawful and unlawful) and their consumption and use are treated in the Qur'an to some extent. In Sura 2:172–173 Allah declares: "O ye who believe! Eat of the good things that We have provided for you and be grateful to Allah, if it is Him ye worship. He

hath only forbidden you dead meat, and blood, and the flesh of swine, and that on which any other name hath been invoked besides that of Allah" (all Qur'an translations by A. Yusuf 'Ali). There is some flexibility for persons who need nourishment in an emergency situation, as the second verse advises, "provided there is no willful disobedience, nor transgressing due limits – then he is guiltless. For Allah is Oft-Forgiving Most Merciful." The Qur'an requires Muslims to eat only meat that has been consecrated to Allah. There are also stipulations about how meat has been slaughtered, obtained, treated, and prepared. Generally, the Qur'an permits Muslims to eat food of the People of the Book – Jews and Christians – which "is lawful unto you and yours is lawful unto them" (5:5).

Pork is of course not permitted for either Muslims or Jews. In addition to the forbidden foods already mentioned, "Forbidden to you (for food) are . . . that which hath been killed by strangling, or by a violent blow, or by a headlong fall, or by being gored to death; that which hath been (partly) eaten by a wild animal. . ." (5:3). And wine or any kinds of intoxicants are not permitted for Muslims at all. The Qur'an states that intoxicants and gambling are part of Satan's plan to "excite enmity and hatred between you [i.e. Muslims] . . . and hinder you from the remembrance of Allah and from prayer: Will ye not then abstain?" (5:91).

There is a sense of the diets of Arabs in the dawn years of Islam's development by mention of specific foods in the Qur'an. In 2:61 the followers of Moses wandering in the wilderness with him and eating manna and quails saying: "O Moses! we cannot endure one kind of food (always); so beseech thy Lord for us to produce for us of what the earth groweth – its pot-herbs, and cucumbers, its garlic, lentils, and onions." The Qur'an mentions several fruits (e.g., pomegranates, dates, figs, grapes, and olives), not in a manner that might remind one of a cookbook but in symbolic ways bearing on the many wonderful "favors" provided by Allah for humans and whether they will be ungrateful, deny, or misuse them. Cow's milk and honey are mentioned (16:66–68) as valuable foods, but not to the extent of fruits. Land game is permitted generally for hunting

and eating, but not for Muslims in sacred precincts such as Mecca and while wearing pilgrim garb (5:96). Catching “water game” (fish, water fowl, etc.) is permitted for Muslims whether at home or while traveling. In 6:141 there is a statement about wonderful foods that Allah has provided for humankind as well as for other living beings (by implication) ending with: “But waste not by excess: for Allah loveth not the wasters.” (A generously detailed, sophisticated article by David Waines, about what has been discussed here, is cited in the Reference List following this essay.)

The Hadith on Food and Drinks

There is a considerable amount about foods and drinks and how they should be obtained and managed in the Hadith literature (the Prophetic Sunna) that reflects what is found in the Qur’an, except that in the Hadith literature it is found in considerably greater detail, extending to social etiquette. The following are some examples of this last category (all quoted from *A Manual of Hadith* 1988):

‘Umar [a leading Companion] said, The Messenger of Allah (peace and blessings of Allah be on him) said: ‘Eat together and do not eat separately, for the blessing is with the company.’ (p. 356, no. 25)

‘Umar ibn Abu Salamah said, ‘I was a boy being brought up in the care of the Messenger of Allah (peace and blessings of Allah be on him) and my hand was active in the bowl, taking from every side.’ So the Messenger of Allah (peace and blessings of Allah be on him), said to me, ‘Boy! Say *Bismillāh* [In the Name of Allah.] and eat with thy right hand and eat from the side nearest to thee.’ So this was my manner of eating afterwards. (p. 352, no. 16)

Hudhaifah said, I heard the Prophet (peace and blessings of Allah be on him) say: ‘Do not wear silk or silk brocade, and do not drink in vessels of gold and silver, and do not eat in bowls made of them; for they are for them in this life and for us in the next. (p. 355, no. 22)

There are examples of Hadith literature elements of a social ethic that are found both in the Qur’an and the Prophetic Sunna traditions. As for Muslim teachings concerning agricultural ethics,

there is a considerable concern for how Muslims should respect and cooperate for the general well-being of the Umma – the worldwide Muslim community – as well as for other peoples with whom they may be neighbors sharing lands, resources, markets, and social as well as political and legal situations and institutions.

Agriculture in the Muslim World

Ibn Khaldūn (1332–1406 CE) was a great Arab historian who traveled far and wide through the Muslim world of his era. He wrote a very influential three-volume work, the *Muqaddimah* (“Preface”), on how he viewed history, science, literature, and much else within the Muslim context. He had studied ancient agricultural texts extensively down to his era and considered *filāha* (agriculture) to be a branch of physics and needing to attend closely both to practical matters such as planting of crops and their treatment, as well as “their preservation from things that might harm them or affect their growth, and all things connected with that.” He wrote that sufficient books “are available” to meet the peoples’ needs in this critically important dimension of life. So, some sort of agricultural ethical discourse was clearly known to be essential in Ibn Khaldun’s time and over many previous centuries in the Muslim world and beyond to ancient times.

Muslims profoundly revere their global faith community, known as the Umma, an Arabic term, and their worship practices reveal this by their relatively uniform character, which is set forth in the Qur’an. But the Qur’an has more to say concerning what can constitute an *umma*: “There is not an animal (that lives) on the earth, nor a being that flies on its wings, but (forms part of) communities [*ummam*, i.e. “ummas”] like you. Nothing have We omitted from the Book, and they (all) shall be gathered together to their Lord in the end” (Sura 6:38). Passages such as this open up the boundaries of what environmental ethics should consider, particularly when humans desire to accept Allah’s invitation to be His vicegerents, “caliphs” (*khalīfa*) on earth. To be a caliph who applies Allah’s environmental teachings in their

stewardship on earth is a major commitment, indeed.

In the present era, there is ever-increasing attention being paid to agricultural and environment ethics by Muslims across the global Umma/community. Numerous websites address this in various ways with essays, reports, invitations to participate, descriptions of specific practices in widely diverse regions of the Muslim world, and much more. While Muslim websites show advanced awareness of and absolute need for contemporary scientific and technological developments and opportunities directed at protecting and conserving agricultural and indeed other important natural environments, as well, they often clearly state the Islamic religious and theological principles and practices that they are committed to as the most important factors in agricultural and environmental ethics. Central to an Islamic agricultural/environmental ethic is a strong commitment to *stewardship* as the means by which Muslims obey and live by Allah's commandments with respect to caring for the magnificent and life-sustaining natural world He created for us and all living creatures.

One website carries a perceptive article by Hanane Karimi that seeks to lead Muslims toward a "sustainable world" by means of an "ethical perspective concerning the environment." This is seen to be a "challenge initiated by eco-theology" based in thorough studies of religious and ethical "resources that make sense for the Believers." Although this website is directed principally toward Muslims, there is a strong sense of welcoming cooperation from dedicated "Believers" of neighboring faith traditions, as well. The author draws equally upon traditional Islamic ethics concerning stewardship of the environment but joins it with modern environmental ethics, particularly as developed by the American environmental activist Aldo Leopold (1887–1948) whose pioneering ecological advocacy and writings, as Karimi remarks: "...put bio-centric ethics into practice, with the conviction that each organism is a teleological center of life of which the value is intrinsic" (Karimi, p. 1).

Another website provides a list of four "Islamic Agricultural Techniques," by Taylor Echols, that

clearly belong in any discourse on agricultural ethics in Muslim contexts. The four techniques (all listed on the single page of the report) are as follows:

"The Islamic Agricultural Revolution." This is the range of processes that enabled the early developing Islamic civilization in the arid and high-temperature regions of the North African to Nile-to-Oxus regions of the world to develop such techniques as advanced irrigation systems, water storage, crop rotations, fertilizers, and related things. The traditional techniques are still of great value alongside modern techniques.

"Water and Irrigation." Continuing need and development, as always, in arid, high-temperature regions.

"Advances in Islamic Agriculture." Advanced tools and processes for cultivation and care of plants and animals. Factory farms are parallel to such increasingly influential developments in the rest of the world, as well. Increased populations generate growing demands for foods of many kinds and in large quantities. Genetically modified food crops are increasingly accepted by Muslim growers and their clients (more on this below).

"Organic Islamic Agriculture." Muslim nations are embracing organic agricultural techniques as is much of the rest of the world. Many Muslims do express concerns about possible violations of legally required *halal* purification practices, because of the potential threat in some organic technical processes in newly invented food product developments which may incorporate *haram* ("forbidden") elements (such as a chemical derived from a pork source).

GMOs: Genetically Modified Organisms in Muslim Contexts

Muslim populations across the Umma tend to permit the development and use of genetically modified organisms (GMOs) for the production of food. Ebrahim Moosa, in a well-researched survey article under the title "Genetically

Modified Foods and Muslim Ethics,” remarks that “What GMOs present are a whole series of challenges about which Muslim ethics is as ambivalent and undecided as other religious traditions. At best, Muslim ethics on a range of bioethical and scientific challenges can be described as a work in progress. Most surprising is the dearth of Muslim ethical deliberations on this topic” (Moosa 2009, p. 140).

Moosa discusses GMOs as “manageable risk,” based on guidelines that the Saudi-based Council for Islamic Jurisprudence (CIJ), which has addressed GMOs since ca. 1998, has set forth. In the guidelines, CIJ declares: “It is permissible to employ genetic engineering and its attendant products in the sphere of agriculture and animal husbandry. This is allowed on condition that all necessary precautions be adopted in order to prevent any kind of harm – even on a long-term basis – to humans, animals and the environment” (Moosa 2009, p. 142). The CIJ insists that all products in the human food and medical chains that have been affected by “genetically engineered substances” should be clearly disclosed to consumers.

Moosa concludes his technically sophisticated article in an open-minded way: “Religious authorities take a very pragmatic approach in evaluating biotechnology associated with GMOs. Since there is no compelling evidence that GMOs can harm the body, coupled with the fact that it is rare that prohibited transgenes are used in food, Muslim religious authorities are willing to give GMO-producing bio-technology the green light. Whether the long-term environmental impact of frontier biotechnology will be subject to serious ethical and moral scrutiny within Muslim quarters is not always evident. However, there is some hope that those who adopt a precautionary approach might be instrumental in expanding the parameters of the debate and thereby bring a larger set of issues and concerns into ethical and discursive purview” (Moosa 2009, p. 155).

Summary

This entry addresses in brief fashion how food and agriculture are understood, produced, and used

within the spiritual, legal, social, economic, ethical, and cultural contexts of Islam, the monotheistic world religion whose name means “submission” to Allah (“God”), by the religion’s followers, who are known as Muslims, meaning “those who have submitted.” Islam has two principal textual sources for its teachings and practices. The scriptural book known as the Qur’an, which means “recitation,” is the most authoritative source for Muslims who believe it descended from Allah to the human being Muhammad, who through this process became a prophet who spread Allah’s divine message for His human creatures to follow and share. The second most authoritative sources are the reports of words and actions of Muhammad that were collected over time by the Prophet Muhammad’s early companions and the steadily growing community of Muslims after the Prophet’s passing. They were eventually compiled into a major collection known as the Sunna. This essay contains quotations on the subject from both the divine Qur’anic scripture and the deeply influential human words and deeds found in the Prophet Muhammad’s Sunna. The essay then proceeds to describe and explain in general how Muslims over many generations have practiced agriculture and cared for the natural environment, which is believed by them to be a commitment to stewardship, caring for God’s created world as His trusted agents. The essay concludes by addressing a revolutionary scientific development for agriculture in today’s world, not only among Muslims but in the earth’s diverse human communities across the global landscape. This area of interest and importance is the increasing use of genetically modified organisms (GMOs) for the production of food.

Islamic Landscapes for Food Practice

► Islam and Food

Jainism and Food

Colleen Taylor Sen
Chicago, IL, USA

Introduction

One of the most remarkable sights in the Indian Subcontinent (a land of many marvels) is a lightly clad man or woman walking along the roadside sweeping the path head with a straw broom. The sweeper is a Jain monk or nun, and the reason for this action is to clear the path of any insects he or she might accidentally step on and kill.

So great is the Jains' reverence for all forms of life that monks will not kill insects that bite them, till the soil which may harbor small forms of life, or eat after sunset lest they accidentally ingest a bug. It goes without saying that the Jains do not eat meat. As one scholar wrote, "To say that Jains are strictly vegetarian hardly begins to convey either the rigour and severity of the rules which some Jains put themselves under or the centrality of such practices to Jain religious life" (Laidlaw 2003, p. 153).

The 2001 Indian Census reported 4.2 million Jains in India, 0.4% of the total population. They are concentrated in Western and Southern India, especially the states of Maharashtra, Gujarat, Rajasthan, and Karnataka. There are also Jain communities in the United States (estimated at between 50,000 and 100,000), the United

Kingdom, and East Africa. However, their significance cannot be underestimated. Vegetarianism and the concept of ahimsa (noninjury), which are central to Hinduism, had their origins in Jain beliefs and practices, while Mahatma Gandhi, although born a Hindu, was greatly influenced by Jainism.

The Emergence of Movements Opposed to Vedic Sacrifice

Both Jainism and Buddhism appeared in the Gangetic Basin (a region extending from modern Pakistan to the state of Bihar) in the sixth century BCE. The movements represented a revolt against what is sometimes called the Vedic religion or Vedism (after the *Vedas*, a collection of prayers, magical incantations, hymns, and poems compiled orally around 1500 BCE). A feature of Vedic society was the development of a caste system, with the Brahmins (priests) at the top. They were all powerful, since only they knew the sacred rituals and could perform the animal sacrifices needed to propitiate the gods – forces of nature with parallels in Greek and Roman mythology.

Somewhat later alternative philosophical and metaphysical ideas were emerging in the forests. One was reincarnation, the idea that there is an endless cycle of births, deaths, and rebirths that is determined by our actions in this world. Under the law of karma, every action has its effects on the future; the sum of our past karma determines our

present existence and our future lives. The goal of existence is not worldly comforts or wealth but to realize this basic truth and attain release from the endless suffering of rebirths by asceticism, meditation, and yoga.

Mahavira Organizes His Followers

The most important figure in Jainism is Vardhaman (believed to have lived 599–527 BCE), whom his followers called Mahavira (great hero). Like Gautama Buddha, he was the son of the ruler of a small kingdom in northeast India. (There is no evidence that the two ever met.) The word Jain means a follower of *jina* (conqueror), *jina* being another name bestowed upon Mahavira because of his self-control. Vardhaman married and had children, but at the age of 30 left home to become a naked ascetic in search of enlightenment.

For 12 years, he wandered around northeast India experiencing many deprivations and hardships. In the 13th year, he attained enlightenment (*kevala*). To Jains, this does not mean union with the Absolute, as in Hinduism, or nothingness, as in Buddhism, but rather pure consciousness and absolute omniscience.

Mahavira was not the founder of a new religion, but is considered the last of 24 *jinas*, called *tirthankaras*, or ford-makers – omniscient teachers who attained enlightenment and then “made a ford”, showing others the path. Like Gautama Buddha, he appears to have been an excellent organizer who attracted disciples, converted many people, and founded monastic orders for both men and women. He organized his followers into a fourfold order consisting of *sadhus* (wandering male ascetics, sometimes called monks or renouncers), *sadhvis* (female ascetics/nuns), *shravaks* (laymen), and *shravikas* (laywomen). While all take the same four basic vows, the renouncers follow them much more strictly and take additional vows. It is they who embody the ultimate ideal of Jainism. They give up their homes, money, and possessions; wander around the countryside in single-sex groups; and depend entirely on laypeople for their food and shelter.

The Basic Beliefs of Jainism

Jainism is essentially an atheistic religion: The universe has existed from all eternity and its changes are due to the inherent powers of nature, not the intervention of a god. All knowledge is relative and temporary; absolute truth comes only to those enlightened people who appear at certain times in history, the *tirthankaras*. Although some Jain temples display their statues, they are not worshipped but are rather regarded as perfect beings to venerate and emulate.

A basic premise of Jainism is that life in the world is essentially bad and painful and that the evil done by humans leads to endless rebirths. The goal of human existence is to break this cycle and end the cycle of rebirths. This can only be accomplished when people can free ourselves from attachment and aversion and attain a state of perfect omniscience. What prevents them from doing this is karma, the effects of bad deeds and thoughts.

The Nature of Karma

Unlike Hindus or Buddhists, Jains view karma not as a spiritual or intangible element, but as a physical substance – a superfine matter that clings to our souls and conforms to mechanical laws of cause and effect. People attract karma particles when they do or say something wrong, such as telling a lie, stealing, or killing a living being. These bad actions cause souls to attract more karma, creating a vicious circle.

Jains believe that a person can avoid the accumulation of karma and remove karma that has already accumulated by behaving and thinking correctly and by having the correct mental state, so that even if an action attracts karma, it does not stick to the soul. This is done by following three ethical principles, called the Three Jewels – right faith, right perception, and right knowledge – and taking five great vows (*mahavratas*): *ahimsa*, nonviolence or noninjury; *satya*, truthfulness; *asteya*, not stealing; *aparagriha*, non-acquisitiveness; and *brahmacharya*, chaste living. All five vows are observed by monks; laypeople only follow the first four.

Ahimsa or Noninjury: The Central Principle of Jainism

The heart of Jain ethics is *ahimsa*, a word sometimes translated nonviolence but more correctly as “not harming.” It is summed up in the statement “Do not injure, abuse, oppress, enslave, insult, torment, torture or kill any creature or living being.” Harm is not only physical but mental and verbal. Related to *ahimsa* is the notion of *daya*, a spirit of compassion towards all living beings.

Properties of Jivas

These concepts are rooted in Jains’ views of the universe, which is seen as consisting of both lifeless things and an infinite number of *jivas*, or living entities, sometimes translated as souls. *Jivas* are made of energy and do not have physical form until they are incorporated into a body. Embodied *jivas* are classified according to their number of senses:

- One sense (touch): clay, sand, rain, ice, fire, wind, trees, bacteria, yeast, flowers, vegetables
- Two senses (touch and taste) worms, leeches, termites
- Three senses (touch, taste, smell): ants, lice, beetles, moths
- Four senses (touch, taste, smell, sight): flies, bees, scorpions
- Five senses (touch, taste, smell, sight, hearing): infernal beings, animals, birds, human beings, and heavenly beings

A further distinction is made between vegetables with only one *jiva* and those that contain a multitude of living organisms, such as underground roots, bulbs, buds, and shoots as well as figs and fruits and vegetables with many seeds.

While in practice it is impossible to survive without killing or injuring some form of being, Jains strive to avoid doing any intentional harm. Thus, they are not supposed to be farmers, because tilling the soil would kill life; perform jobs involving fermentation, digging, and selling

weapons or pesticides; or trade in meat products, honey, eggs, silk, or leather.

Wandering monks wear masks to avoid breathing in small *jivas* and sweep the ground in front of them with a broom as they walk. During the monsoon season, they stay in indoors as much as possible, because the world is teeming with life at this time. A worshipper cannot enter a Jain temple wearing animal products. Renouncers are enjoined against traveling except on foot.

Jains establish animal sanctuaries and hospitals for cows, birds, and other animals. They free the birds when they recover, since they do not believe in confining them; for the same reason, contemporary Jains generally do not keep household pets.

Permitted and Banned Foods

Nowhere do Jain concerns about *ahimsa* manifest themselves more vigorously than with regard to food. While *all* observant Jains avoid certain foods that are absolutely forbidden, including meat, fish, and eggs, there are variations in what they otherwise eat, depending on family customs, sect, age, sex, time of year, personal circumstances, etc. In general, the old follow more restrictions than the young and women more than men; often people allow themselves greater latitude outside their homes. The practice of *ahimsa* and vegetarianism are on a continuum: As a Jain progresses on his or her spiritual journey, he limits the kind and number of foods he consumes.

From the eleventh century onward, Jain texts contain detailed lists of what can and cannot be eaten. Five things are absolutely forbidden for all Jains: meat (including meat products, such as gelatin), fish, eggs, alcohol, and honey. Eating meat is absolutely unthinkable; one renouncer is quoted as saying, “Meat-eaters have the shape of humans but they are not really human” (Laidlaw, p. 67). In India, many Jains will not frequent stores where meat, fish, or eggs are sold and will pay the owners of slaughter houses not to kill animals on certain holidays.

Alcohol is reviled because the process of fermentation and distillation multiplies and destroys

living organisms and because it clouds one's thinking and can lead to violence. Honey is banned because it contains the bodily secretions of bees; if the bees are smoked out ahead of time, it destroys other insects that took their place.

In India, most Jain and Hindu vegetarians are not vegans, perhaps because the need for the nutrients in milk products was so important and because cows are (at least in theory) treated kindly. However, some North American Jains do avoid milk and dairy products because of the violence involved in producing milk by machines and the fact that cows are killed when they stop producing (Jain et al. 2005, p. 20).

Other food items are off-limits to renunciators at all times and to laypersons during certain fasts. These items include:

- Fruits and vegetables with many seeds, including figs, pomegranate, guava, and tomatoes
- "Empty fruits," that is, fruits with little nutritional value
- Vegetables that grow underground, including potatoes, turnips, squashes, carrots, radishes, and mushrooms
- Onions and garlic
- Fresh ginger and turmeric
- Foods containing yeast
- Nonvegetarian cheese
- Cauliflower and cabbage
- Buds and sprouts, including sprouted lentils
- Rotting and stale food

Fruits with many seeds are banned because each seed encloses the germ of life. Pulling up root vegetables kills millions of *jivas* in the soil, and the plants themselves contain an infinite number of *jivas* so that even a tiny part will grow if planted. Insects live within the leaves of cauliflowers and cabbages. Turmeric and ginger are not eaten fresh but may be eaten as dried powdered spices since in this form they cannot grow again.

Ayurvedic theories of medicine and folk beliefs reinforce these selections. Throughout India, onions and garlic are believed to inflame the passions and destroy mental equilibrium and thus are avoided by many orthodox Hindus. The orthodox of any religion are suspicious of what is

new and foreign, which may account for the ban on such New World products as tomatoes, potatoes, and guavas.

Traditionally, Jains avoid eating after sunset, since they may inadvertently destroy unseen live forms and drink only boiled and filtered water in order to minimize the consumption of minute water-borne organisms. Jain writings contain detailed rules about how long foods can be kept before eating. For example, milk must be filtered and boiled within 48 min of milking the cow; yogurt should not be more than 1 day unless it is mixed with raisins or other sweetening agents; flour is to be kept for only 3 days in the rainy season and 7 days in the winter; and sweets must be consumed within 24 h (Mahais 1985, p. 105). Although these rules may no longer be relevant because of modern refrigeration, they reflect a sophisticated knowledge of hygienic and health issues at an early date.

The Jain Diet

There is no Jain cuisine as such. Until recently, most Indian food was produced locally and was highly seasonal. Jain food is also largely regional. Its dietary staples are grains and legumes. In Western India, the traditional grains were millet and sorghum, in North India wheat, grounded into flour and made into unleavened breads. Grains may also be coarsely ground and boiled to produce *daliya*, a kind of porridge. In Eastern India, boiled rice is the standard staple.

Legumes are boiled and spiced to make the soupy dish called *dal*. Hing, or asafetida, is a common replacement for garlic. There is no restriction on the myriad of spices that are the distinctive feature of Indian cuisine and impart flavor and aroma to the simplest of vegetarian dishes. Tropical fruits such as mango, coconut, and green vegetables are part of Jains' daily fare. In Rajasthan, much of which is a barren desert, substitutes for vegetables in stews and curries are made from ground grain or lentils boiled and dried in the sun.

Because Jains are not vegans, dairy products are an important part of their diet that provide needed nutrients. They include yogurt, buttermilk, and ghee – clarified butter. In India, ghee was

traditionally associated with opulence and good health and affluent Jains are known for the amount they use in their cooking. Indians in general love sweets, made of sugar, dairy products, nuts, and spices, and Jains are no exception, although they give them up during fasts.

Jains abroad adapt to local conditions. A young Jain professional reports he does his best to avoid harming life “to the extent possible and practicable.” He never consumes meat, fish, or eggs but will eat onions, garlic, and root vegetables. When dining with friends, he frequents Italian, Thai, and Japanese restaurants which serve vegetarian fare. He eats a lot of cheese, but does not insist on vegetarian cheese (i.e., cheese made without using whey, casein, rennet, or other animal products as coagulating agents). In Thai restaurants he requests that the vegetarian dishes be prepared without fish sauce. In Japanese restaurants, he eats vegetarian sushi.

Fasting

An important way of removing negative karma is by fasting, which Jains have elevated to an art form. (Jain fasting served as an inspiration for Mahatma Gandhi, who used it as a political tactic). The Hindi word for fast, *tapas*, means “heat” in Sanskrit: A common metaphor is that just as the sun dries up a polluted lake, so fasting purifies the soul by removing negative karma. Fasts are considered essential for spiritual growth.

A fast is always preceded by a vow, which means that it is a religious act and done with a predefined intention. There are no hard and fast rules when or how long one should fast or what form this fasting should take, but it is never obligatory, always a matter of free will. It is not enough just to stop eating; one should also lose the desire to eat and not relish food when one does eat. Fasting is not done in isolation but with one’s family or as a community event.

Fasts are both an extension and intensification of Jains’ regular dietary restrictions. Jain texts classify fasts into many categories and lay down complex rules about what can and cannot be eaten. For example, fasting may mean giving up

all food and water for 1 day, 3 days, or 8 days; every alternative day of the year; twice a year; etc. It can entail drinking only water or the water used to rinse out a pot. Fasters may eat only one meal a day at a set time; limit the number of items eaten; give up favorite foods, such as sweets (sometimes on a permanent basis); or eliminate salt or spices from their diet. A common form of fasting requires giving up green vegetables, milk, yogurt, oil, fruits, salt, spices, and sugar and eating only dal and rice.

Like some Hindus, Jains fast on certain days of the lunar cycle when the moon changes, especially the 8th and 14th day of each fortnight. They fast when the seasons change and during the monsoon, when fasting is thought to also offer protection against illness. Most Jains fast during festivals, especially *Paryushan Maha Pava* which lasts 8–10 days during the rainy season (usually in August–September). Some fast for the entire period, others for shorter times, but fasting on the final day is considered obligatory. In this case, fasting means complete abstinence from any sort of food or drink, but some people take boiled water during the daytime. During this festival people ask forgiveness of those they have offended, visit the temple, and celebrate with a community feast.

However, Jains may fast at any time, especially if they believe have committed a sin and need to repent. Women generally fast more than men and the old more than the young; after retirement, some people start to fast on a regular basis.

The ultimate fast, called *smadhi maran* or *sallekhna*, involves giving up all food and water and starving oneself to death. This practice is undertaken by someone who is the final stages of a fatal illness or is very old and feels they have fulfilled their duties in this life. They must have permission from a senior renouncer, which is granted only if death is imminent. The practice has been challenged in the Indian courts.

Impact of Jainism

The basic concepts of Jainism were ultimately absorbed by the religion that came to be known

as Hinduism, especially vegetarianism and the concept of ahimsa, which became the centerpiece of the teaching of Mahatma Gandhi. Although born a Hindu, Gandhi grew up in a community in Gujarat where there were many Jains and as a young man had a Jain spiritual adviser. He is quoted as saying:

No religion of the World has explained the principle of Ahimsa [nonviolence] so deeply and systematically as discussed, with its applicability in life, in Jainism. As and when this benevolent principle of Ahimsa will be sought for practice by the people of the world to achieve their ends of life in this world and beyond, Jainism is sure to have the uppermost status and Bhagwan [a term of respect] Mahavira is sure to be respected as the greatest authority on Ahimsa. (Jain Centre 2002)

Summary

The only religion in the world that is unconditionally vegetarian is Jainism, which has around four million adherents, mainly in Western India. Jainism developed in India in the sixth century BCE; its leading figure, Mahavira, was a contemporary of the Buddha. Both religions opposed the increasing power of the Brahmins and animal sacrifice. The Hindu practice of vegetarianism may have originated with the Jains.

The cardinal principle of Jainism is *ahimsa*, translated as noninjury or nonviolence. Jains believe that every organism, from single cell amoebas to human beings, has an eternal soul, or *jiva*. Thus, any injury to any creature, however lowly, must be avoided. Jains are not allowed to follow farming as a profession because of the harm to creatures in the soil.

Jains not only do not eat meat, fish, or eggs, but they avoid a myriad of other foods, including any whose production kills the plant, harms microscopic organisms, or destroys the germs of future life. Thus, Jains avoid honey, fruits and vegetables with little seeds (eggplant, figs), underground roots (potatoes, carrots, onions, etc.), and mushrooms. Milk and milk products are allowed but alcohol is forbidden. Jain monks and nuns follow every more stringent dietary restrictions, than lay persons. This essay will describe the history of Jainism and its main philosophical tenets, with a focus on its dietary restrictions and prescriptions.

Jefferson's Moral Agrarianism

Introduction

Thomas Jefferson wore numerous hats: that of statesman, meteorologist, inventor, religionist, historian, architect, ethicist, philologist, humanitarian, paleontologist, botanist, and farmer, inter alia. In none of those disciplines could he claim expertise – he never did – but in none of those disciplines was he a mere dilettante. In that regard, he stood head and shoulders above all other US presidents and head and shoulders above all others of his day, except for a select few.

Among his numerous passions, Jefferson expressed especial affection for farming. Upon retirement from politics, he writes to John Adams, “I return to farming with an ardor which I scarcely knew in my youth, and which has got the better entirely of my love of study” (25 Apr. 1794). “If you visit me as a farmer,” he states to W. B. Giles 1 year later (27 Apr. 1795), “it must be as a co-disciple. . . . I am as much delighted and occupied with it, as if I was the greatest adept. I shall talk with you about it from morning till night, and put you on very short allowance as to political aliment.” Sixteen years later, he writes C. W. Peale (20 Aug. 1811) of being an “old man,” but a “young gardener.” “No occupation is so delightful to me as the culture of the earth, and no culture comparable to that of the garden,” he adds. “Such a variety of subjects, some one always coming to perfection, the failure of one thing repaired by the success of another, and instead of one harvest a continued one through the year.”

“Liberal Eudaimonism”

Jefferson's passion for agrarianism is a consequence of his broad-scale ethical views – what may be dubbed his “liberal eudaimonism” and which comprises liberalism, eudaimonism, meritocracy, and progressivism.

Jefferson's liberalism comprises purchases of “freedom from” (negative liberty) and “freedom to” (positive liberty). Jefferson's conception of liberty is a code of restraint on sovereignty, exercised by a few or many – i.e., negative liberty.

Freed from potential abuse through political intervention in their affairs, citizens are at liberty to manage their own affairs as they see fit to do so. Yet recognizing that liberty was no end in itself, Jefferson recognizes the need of some government intervention in citizens' affairs to promote human flourishing – i.e., freedom to. For instance, he proposed a constitutional amendment in 1806 to allow for improvements toward the general welfare – viz., the opening of roads, clearing of rivers, and building of canals.

“Eudaimonism,” drawn from Aristotle's and the Greek and Roman Stoics' view of *eudaimonia* (commonly translated as “happiness”), is the view that the best manner of living is to live well or to flourish. Jefferson is a eudaimonist of some persuasion. His addresses and correspondence – e.g., to John Adams, 28 Feb. 1796, and to Pierre Samuel Dupont de Nemours, 24 Apr. 1816 – especially show that he has a very definite notion of the good life, which critically involves virtuous activity through exercise of the moral sense as well as some stock of bodily and external goods. As is the case with the eudaimonism of Aristotle and the Greek and Roman Stoics, human happiness for Jefferson involves no separation of public and private dimensions.

Meritocracy, for Jefferson, involves four tiers of government – wards, counties, states, and the nation – in place so that everyone has some participatory role in governing. Key, however, he writes to John Adams (28 Oct. 1813), is that the talented and morally superior – i.e., the natural aristocracy (*aristoi*) – will most likely be encouraged to govern at the higher levels. The way to ensure that the naturally best and not the artificially best rule is to leave the election of governors in the hands of the people, suitably educated. Jefferson even claims that having the best rule is the best test of a good government.

Jefferson's writings – e.g., to Joseph Priestley, 27 Jan. 1800; to Count de Moustier, 17 May 1788; to Elbridge Gerry, 26 Jan. 1799; and to William Green Munford, 18 June 1799 – also show that he consistently clung to the belief that humans as a whole were progressive beings. In keeping with the general trend of Enlightenment thinking, Jefferson believed that the human mind and the

moral sense were massively underdeveloped and, thus, capable of substantial improvement. There were Bacon in philosophy; Boyle, Brahe, Galileo, Kepler, Rittenhouse, and Newton in science; Locke and Sidney in political theory apropos of human intelligence; and Kames, Priestley, Sterne, and Hutcheson in moral theory. Following the lead of such progressivists, Jefferson's republican ideals were directed toward maximizing intellectual, political, and especially moral improvement to promote human flourishing.

Agrarianism as Moral Nonesuch

Agrarianism had an especial place in Jefferson's notion of the good life. The life of a farmer, he thought, was suited ideally to promote large-scale human flourishing by enhancing independence of all citizens, allowing both for some measure of political participation through the leisure provided by scientific farming and for cultivating virtue through honest and valuable labor. "Corruption of morals in the mass of cultivators is a phenomenon of which no age nor nation has furnished an example," he writes in Query XIX of his *Notes on Virginia*. "It is the mark set on those, who, not looking up to heaven, to their own soil and industry, as does the husbandman, for their subsistence, depend for it on casualties and caprice of customers." "The pursuits of agriculture . . . are the best preservative of morals," he writes to John Blair (13 Aug. 1787). "Agriculture is our wisest pursuit, because it will in the end contribute most to real wealth, good morals and happiness," he tells George Washington (14 Aug. 1787).

Agrarianism for Jefferson is, thus, a moral ideal. He states famously in Query XIX of *Notes on Virginia*, "Those who labor the earth are the chosen people of God, if ever he had a chosen people, whose breasts he has made his peculiar deposit for substantial and genuine virtue." He iterates that sentiment in Query XXII, where he says no age of history has ever recorded corruption in the "mass of cultivators." To James Madison (20 Dec. 1788), he writes, "I think our government will remain virtuous for many centuries; as long as they [*sic*] are chiefly agricultural;

and this will be as long as there shall be vacant lands in any part of America. When they get piled upon one another in large cities, as in Europe, they will become corrupt as in Europe." To Jean-Nicolas D  meunier (29 Apr. 1795), Jefferson writes that husbandry yields "the most happiness & contentment to one of . . . philosophic turn."

Query XIX of his *Notes on Virginia* gives Jefferson's fullest expatiation of agrarianism as a moral ideal. In Europe, people are forced into manufacture, as the surplus of people and want of land make agriculture difficult. The costs on human happiness are great. In America, there is a surplus of land and a want of people to improve it. Americans, as farmers, are self-sufficient and dedicated to their land, state, and country.

Farmers, not manufacturers, are self-sufficient, for manufacturers are dependent on the "casualties and caprice of customers" and dependence leads to subservience, venality, ambition, and suffocates virtue. Americans lack many of the goods of Europe, he concedes, but they are better for that, as such "goods," mere bagatelles, lead to loss of independence and unhappiness. "Generally speaking," he writes, "the proportion which the aggregate of the other classes of citizens bears in any state to that of its husbandmen, is the proportion of its unsound to its healthy parts, and is a good-enough barometer whereby to measure its degree of corruption."

The consistent message in *Notes on Virginia* – that agrarianism is the most virtuous life – is spelled out in several letters. Jefferson writes to Caspar Wistar (21 June 1807), "I am not a friend to placing growing men in populous cities, because they acquire there habits & partialities which do not contribute to the happiness of their after life." Elsewhere (e.g., to John Jay, 23 Aug. 1785; to James Madison, 20 Dec. 1787; to Jean-Nicolas D  meunier, 29 Apr. 1795; and to Jean-Baptiste Say, 1 Feb. 1804), he says much the same.

The tone in all such letters is that agrarianism is a moral, not economic ideal. Jefferson's commitment to agriculturalism was a commitment to freedom, virtue, and equality, not a commitment to an economic system. He writes to Thomas Cooper (10 Sept. 1814), "And with the laborers of England generally, does not the moral coercion of want subject their will as despotically to that of

their employer, as the physical constraint does the soldier, the seaman or the slave?" To Thomas Diggs (19 June 1788), Jefferson says that a manufacturer, transplanted from Europe, would be irresistibly tempted by the independence and well-being of the American farmer and would choose an agrarian lifestyle to his prior life of manufacture. That, of course, is not to say that Jefferson did not have some economic and political motives behind his agrarianism. As Query XIX shows, he did. It is merely to emphasize that Jefferson's agrarianism was chiefly moral and that the arguments on behalf of agrarianism as a way of life were principally evaluative and only secondarily economic or political.

Agrarianism as a Universal Standard

Jefferson appeals to nature to ground moral agrarianism. Agrarianism was for him a moral ideal, because it was closest to nature and nature for Jefferson had a normative slant as it did for his beloved ancients (e.g., the Stoics). By nature, husbandry is cornucopian, while manufacture is fruitless. To Benjamin Austin (9 Jan. 1816), he writes, "Agriculture is productive, manufacturing is sterile, and it is nature that makes this so." He adds, "To the labor of the husbandman, a vast addition is made by the spontaneous energies of the earth on which it is employed: for one grain of wheat committed to the earth, she renders twenty, thirty, and even fifty fold, whereas to the labor of the manufacturer nothing is added." The implicit conclusion is that persons ought not to waste time and effort in activities that are by nature sterile.

It might be supposed that Jefferson's moral agrarianism was a normative ideal applicable to Americans, only because they have surfeit of land and the land is underpopulated, but not to non-Americans (e.g., the British or French), because they have want of land and the land is overpopulated. If so, then moral agrarianism is to be taken as a relative or parochial ideal, applicable to Americans and others, situated similarly. For countries with large populations and little land, a different standard of happiness is applicable. That I shall show is not the case. Jefferson was

consistently clear that agrarianism was a standard uniquely idoneous to human nature. For the most part, only people that worked the land could be virtuous and happy.

Jefferson is clear that the life of manufacture that predominates in parts of Europe comes at the expense of human happiness (letter to James Madison, 20 Dec. 1787). He writes John Jay (23 Aug. 1785): "I consider the class of artificers as the panders of vice & the instruments by which the liberties of a country are generally overturned." He adds: "Cultivators of the earth are the most valuable citizens. They are the most vigorous, the most independent, the most virtuous, & they are tied to their country & wedded to it's [*sic*] liberty & interests by the most lasting bonds." When there is no longer arable land for farming, those citizens unable to farms should become mariners before manufacturers. His judgments in such letters are not circumstance-dependent, but absolute.

Jefferson's letter to Jay shows agrarianism ties one to the land and that suggests a sort of bondage, not independence. For Jefferson, there can be no notion of independence without some form of yoke. The only liberty worth having is that of a farmer, who is tied to his land and thus to his state and who has work that frees him from the drudgery of manufacture. Manufacturers, following self-interest alone, are yoked to the caprice of consumers. Farmers, following a more patriotic course, are yoked to self-interest as well as the interests of their state.

For Jefferson, husbandmen have a link to the land that manufacturers, tradesmen, and merchants do not. In times of economic distress or war, the latter can liquidate their assets and abandon the state; husbandmen can do no such thing. Husbandmen have an investment in the land and, thus, an investment in their state that others do not have. That investment is not just political; husbandry is character enriching. It is a universally applicable moral ideal.

The Scientific Farmer

Jefferson's *Literary Commonplace Book* (§788) – a compilation of notes taken by Jefferson in his early

years that is 123 pages in length and comprises sections on prose, poetry, and dramatic verse – provides additional confirmation. Here Jefferson jots down three ideas from Montesquieu's *The Spirit of the Laws*: "The cultivation of the earth is the greatest work of man. The more climate brings man to flee work, the more religion and the laws ought to excite them to it. ch. 6. [*sic*] In order to conquer the laziness of climate, it would be necessary that they look to avoid all ways of life without work. ch. 17 [*sic*]" (Jefferson 1989).

In short, agrarianism ties men to their land and country as well as their country's liberties and interests. It is a Ciceronian moral ideal – one in which what is morally beneficial and what is politically beneficial are not dissociable.

There are also Jefferson's observations of the French and British.

In France, conjugal love or domestic happiness does not exist. The French "nourish and invigorate all [their] bad passions." That affords them "moments of ecstasy," he writes to Charles Bellini (30 Sept. 1785), at the price of "days and months of restlessness and torment." To Anne Willing Bingham (7 Feb. 1787), he adds that every person is preoccupied with finding pleasure in the present. Consequently, they are consumed with an ennui, unknown to Americans. "In America, on the other hand, the society of your husband, the fond cares for the children, the arrangements of the house, the improvements of the grounds, fill every moment with a healthy and an useful activity," he writes. "Every exertion is encouraging, because to present amusement, it joins the promise of some future good. The intervals of leisure are filled by the society of real friends, whose affections are not thinned to cob-web, by being spread over a thousand objects."

In England, he writes John Bannister (15 Oct. 1785), things are less deplorable, but also depraved. Britain is a manufacturing society; English education amounts to drinking, horse racing, and boxing. As a manufacturing society, however, they produce splendid goods, yet their splendor is at bottom extravagance, evidence of depravity, and dissipation. "The mechanical arts in London are carried to a wonderful perfection," he writes to boyhood friend John Page (4 May 1786). "But of these I need not

speak, because of them my countrymen have unfortunately too many samples before their eyes. I consider the extravagance which has seized them as a more baneful evil than toryism was during the war."

Jefferson's moral agrarianism – a picture of the good life for all humans everywhere – must not be apprehended as a backward-looking, filiopietistic pastoralism in the manner of Hesiod in *Works and Days* or Virgil in *Georgics*. Instead moral agrarianism is a bucolic ideal that is, in the spirit of the progressivist element of his liberal eudaimonism, quintessentially scientific, progressive, and forward looking. Thus, agrarianism for Jefferson, in keeping with the progressivism of the Enlightenment, is a melioristic ideal that preaches the self-sufficiency and autonomy of an agrarian lifestyle, while it advocates science and technology sufficient to make that lifestyle efficient enough both for domestic leisure and for some measure of local political participation – each an essential component of successful republicanism (Holowchak 2011).

The Problem of Manufacture

Jefferson was not oblivious to the growth of manufacture in the newly formed United States in his lifetime. In a letter to George Washington (15 Mar. 1784), Jefferson acknowledges the influence of commerce and its manufacture. "All the world is becoming commercial. Was [*sic*] it practicable to keep ourselves separated from them we might indulge ourselves in speculating whether commerce contributes to the happiness of mankind." He writes to David Humphreys (23 June 1791) that he endorses America's gradual move toward manufacture. A letter to Jean-Baptiste Say (1 Feb. 1804) 13 years later states, "the best distribution of labor is supposed to be that which places the manufacturing hands alongside the agricultural; so that the one part shall feed both, and the other part furnish both with clothes and other comforts." To Thomas Leiper (21 Jan. 1809), he acknowledges that political autonomy depends on manufacture as well as agriculture. To Governor James Jay months later (7 Apr. 1809), he says that "equilibrium of agriculture, manufactures,

and commerce” is needed for American independence. To Benjamin Austin (9 Jan. 1816), he writes that some amount of manufacture is needed to secure independence: “[Whoever] is against domestic manufacture must be for reducing us either to dependence on that foreign nation or to be clothed in skins, and to live, like wild beasts, in dens. . . . I am not one of these; experience has taught me that manufacturers are now as necessary to our independence as to our comfort.”

Such passages might seem to suggest some amount of whiffle waffling on moral agrarianism or perhaps, at some point, a change of mind. It is clear Jefferson saw the rise of manufacture in America occurring before his own eyes. It is also clear he recognized in time that political independence required both manufacture and agriculture.

Jefferson’s praise of the virtues of farmers never excluded manufacture. Early letters show that. His letter to Jay (23 Aug. 1785) – in which he calls farmers the “most valuable,” “most vigorous,” “most independent,” and “most virtuous” citizens – merely bids citizens to pursue an agrarian lifestyle, so long as there is arable land, in preference to other occupations. “I think our government will remain virtuous for many centuries,” he writes Madison (20 Dec. 1787), “as long as they are chiefly agricultural; and this will be as long as there shall be vacant lands in any part of America.” If there was any change of mind for Jefferson, it concerned the extent to which the agrarian ideal could be instantiated.

Awareness of the need of manufacture and need of commercial exchange for political independence do not show that Jefferson ever abandoned agrarianism as a moral ideal. They show merely that Jefferson was committed only to some amount of manufacture and commercial exchange, sufficient to secure independence, not so much to unseat agriculture as an ethical ideal.

Summary

Thomas Jefferson had an Arcadian vision for his fledgling country. That vision comprised simple, idyllic, and campestrial living. Farms would stretch out from coast to coast and Americans

would engage in only that amount of manufacture to keep them independent of the political bickering of European nations.

Close scrutiny of his writings shows that the motivation for Jefferson’s political and economic agrarian alternative to European living is a moral vision of human flourishing that aims to be a universal standard for humans. Agrarianism for Jefferson is a moral ideal.

Introduction

Many of the laws and commandments that lie at the root of Judaism set out rules for how the community of Israel is required to relate to the production, distribution, and consumption of food. The commandments of the Torah (the five books of Moses that stand at the core of the Jewish scriptures) are defined and supplemented by an elaborate oral tradition embodied in the Talmuds and other works by the rabbis over the ages. The present entry deals primarily with the Jewish dietary laws (“kosher” food) with special reference to the diverse interplay between ritual aspects (aimed at instilling holiness in the lives of Jews) and ethical issues that arise in the production of food, notably matters involving the humane treatment of animals. The advent of modernity has given rise to an intensifying of ethical questions sparked by the industrial mass production of food (especially of meat) and by increased sensitivity to ethical concerns.

Relevant Ethical Principles

In Rabbinic Judaism, ethical questions are often framed in terms of law, though the relationship between law and ethics is not always easy to define. In particular, there exists a flexibly defined realm of “within the line of the law” (analogous to the English “beyond the letter of the law”) which comprises moral behavior that is not enforceable by the judiciary and yet is regarded as part of the structure of religious law.

The Prohibition Against Causing Suffering to Animals

Jewish religious law – “*halakhah*” – forbids the inflicting of unnecessary suffering on animals [*ša‘ar ba‘alei ḥayyim*]. Most authorities understand that this is implicit in Exodus 23:5 which commands to ease the burden of an animal even if it belongs to a personal enemy. Differing views have been expressed as to when the suffering should be classified as “unnecessary”; some of these views, as they relate to agricultural activities and food preparation, will be discussed below. The imperative of humane treatment of animals became an important issue, for example, in modern Israeli farming when dealing with the talmudic prohibition of milking cows on the Sabbath. Concern for the pain that would otherwise be caused to the cows motivated rabbis to devise permissible ways of milking, whether by means of ingenious legal constructions or with the help of technological solutions (automatically timed milking machines) (Steinberg 1979; Schwartz 1997).

The Prohibition Against Destroying Food

Deuteronomy 20:19 states “When thou shalt besiege a city a long time, in making war against it to take it, thou shalt not destroy the trees thereof by wielding an axe against them; for thou mayest eat of them, and thou shalt not cut them down; for is the tree of the field human, that it should be besieged of thee?” Talmudic law understood this as an interdiction against wanton destruction of any fruit-bearing trees. Protection was extended to the fruit itself, and the law forbids any other kind of wasteful spoiling by direct or indirect means, such as hunting for sport or diversion of water sources. This principle has come to serve as a central foundation for recent attempts to incorporate ecological and environmental criteria into religious law, including the dietary regulations (see below) (Zevin 1969). Earlier treatments of the topic were often limited by their acceptance of the doctrine ascribed to Aristotle that divine providence prevents the extinction of entire species (e.g., Maimonides, *Guide* 3:17).

Torah and Vegetarianism

The biblical narrative depicts the earliest stage of humanity as essentially vegetarian. The first man and woman were instructed to eat only from the fruits of the trees in the garden of Eden, and it was only after the flood in the days of Noah (Genesis 9:3) that God told the survivors “Every moving thing that lives shall be food for you, and as I gave you the green plants, I give you everything.” While this suggests that [vegetarianism](#) is an ideal state reflective of humanity’s original vocation, biblical law and practice make it amply clear that the slaughter of animals and consumption of meat are not merely a concession to human weakness, but a central requirement of sacrificial worship and other aspects of Israel’s religious life. At any rate, notwithstanding the diversity that usually characterizes Jewish theology and exegesis, no one has challenged the basic premise that humans occupy a higher plane of the spiritual hierarchy than other living creatures.

The Jerusalem and Babylonian Talmuds (*j.Kilaim* 9:4 [32b]; *b.Bava Mešia* 85a) tell a remarkable legend about Rabbi Judah the Patriarch being approached by a young calf that was pleading to be saved from the slaughterer’s knife, but Rabbi Judah dismissed him saying “This was what you were created for.” As punishment for his indifference, Rabbi Judah was subjected to a severe and prolonged toothache that did not cease until he redeemed himself by showing compassion to a nest of rodents. There is no suggestion that the author of this story was calling for avoidance of meat on ethical grounds – but nevertheless, feelings of compassion toward animals are nonetheless to be expected from decent and pious people, in emulation of the divine quality expressed in Psalms 145:9: “The Lord is good to all, and his tender mercies are over all his works.” Even an influential thinker such as Rabbi Abraham Isaac Kook (1865–1935) who promoted the ideal of vegetarianism as part of his eschatological vision (and is often described incorrectly as being himself a vegetarian), was opposed to its practice as long as the world remains unredeemed (Rosenak 2007, pp. 358–364).

Distribution of Produce

The Torah and much of talmudic literature were composed against a background of peasant life. The Israelites to whom they were addressed lived off the land for the most part, sustaining themselves through farming or husbandry. Biblical law contains elaborate instructions for setting aside certain portions of produce that must be distributed to various recipients, such as the poor, or (what sometimes amounted to the same thing) the Levites and priests who possessed no land of their own and would therefore rely on those portions for their subsistence and to enable them to pursue their spiritual tasks. A “poor tithe” was to be paid on the third and sixth year of every seven-year cycle. Similarly, during the harvests of the respective crops, the Torah designated portions of the produce that must be left for the poor. These include the “border of the field,” the forgotten sheaves and olives, and the gleanings of the vineyard (Leviticus 19:9–10; 23:22; Deuteronomy 24:19–20). All of these practices were defined with precision in rabbinic law, especially in the tractates *Pe’ah* of the Mishnah and Jerusalem Talmud which include descriptions of sophisticated municipal social welfare structures for the collection and distribution of food for the local and indigent poor. The Torah regards these portions as belonging to the poor by moral and legal right and not subject to the vagaries of the donors’ generosity.

Underlying the scriptural institutions of sabbatical and jubilee years (see Exodus 23:10–11; Leviticus 25; Deuteronomy 15:1–10) was an ambitious agenda that combined theological, social, and environmental dimensions. Whereas the command to leave the fields fallow every seventh year might serve a pragmatic purpose in restoring nutrients to the soil, the Torah also incorporates that command into far-reaching social legislation such as leaving produce for the poor and beasts of the field, cancellation of debts, emancipation of slaves, the restoration of ancestral properties to their original owners (who had likely sold them out of economic duress), and other measures that convey the profound ideal that “the land is mine [God’s], for ye are strangers

and sojourners with me” (Leviticus 25:23). Evidence indicates that sabbatical years (at least, their agricultural aspects) were observed quite rigorously in Second Temple and talmudic times; though in modern times, the dominant tendency among religiously observant Jews has been to circumvent the more burdensome prohibitions by means of legal fictions or by relying on imported produce (the restrictions are understood to apply only in the land of Israel).

Seeking Reasons for Dietary Laws

A characteristic feature of biblical writing is its tendency to refrain from supplying explicit reasons for the commandments. In many cases, the reasons may be self-evident, while in some instances (particularly in ritual and cultic matters), religious virtue may well lie in the simple readiness to obey a divine commandment *qua* commandment, without seeking a more specific rationale. There are cases in which the tradition is altogether ambivalent about whether a given law was commanded as an ethical precept or as a sacramental or disciplinary ritual.

This ambivalence is very evident in some of the dietary laws, which include several components that lend themselves to ethical interpretations, though those interpretations are not spelled out explicitly in the official texts and are not necessarily authoritative. Indeed, rabbinic discourse often prefers to deal with the mechanics of religious laws independently of their theological or moral foundations. Although the ethical and the theological aspects are both essential components of Torah law, the conceptual terminology of rabbinic discourse distinguishes between the social and the ritual realms – those commandments that involve the relationship “between a person and one’s neighbor” as distinct from those that are “between a person and the Almighty” (*bein adam leḥavero*, *bein adam lammaḳom*).

For example, Leviticus 11 and Deuteronomy 14 set guidelines for distinguishing between permissible and forbidden species of land animals, birds, aquatic creatures, and insects. The rules are

justified in terms of purity and holiness, not morals or ethics. Edible quadrupeds are identified only by physical criteria: they must chew their cuds and have cloven hooves. However, some commentators, such as Don Isaac Abravanel (1437–1508) noted that all the animal species that are permitted under that definition are peaceful herbivores; they do not possess the sharp teeth or claws that would equip them to be predators. The forbidden birds enumerated by the Torah are also predatory by nature, and to some extent, the same principle can be extended to sea creatures as well.

This kind of exegetical ambivalence pertains to some other scriptural dietary laws that are more likely to be rooted in ethical concerns, such as not seething a kid in its mother’s milk (Exodus 34:26; 23:19; Deuteronomy 14:21), which rabbinic law expanded into the complete separation of dairy and meat. The same ethical interpretation might apply to the precepts “a cow or a ewe, you shall not kill both her and her young in one day” (Leviticus 22:28) and “if a bird’s nest chance to be before thee in the way in any tree, or on the ground, whether they be young ones, or eggs, and the dam sitting upon the young, or upon the eggs, thou shalt not take the dam with the young: but thou shalt in any wise let the dam go, and take the young to thee” (Deuteronomy 22:6–7). All these precepts can be interpreted as intended to avoid acts of real or symbolic cruelty in recognition of the maternal instincts common to all living creatures (thus Rashbam, S. D. Luzzatto, and others); however, several Jewish commentators (including Naḥmanides, Baḥya, and others) explained the latter two precepts on ecological grounds, as being motivated by pragmatic concerns for possible depletion of the fowl supply. As regards the “bird’s nest” precept, the issue was especially confused by a passage in the Mishnah (*Berakhot* 5:3, *Megillah* 4:9) that forbids the liturgical formula “your mercies extend unto a bird’s nest” (a formula that has in fact survived in a Palestinian Aramaic *Targum*). An authoritative opinion in the Talmud (b.*Berakhot* 33b; b.*Megillah* 25a) explains the reason for this liturgical prohibition as “because one is thereby treating the qualities of the Holy One as if they were based on mercy, whereas they are

really absolute decrees.” The severe difficulty that this text placed in the way of Jewish ethical thinkers is particularly apparent in the writings of the great codifier and philosopher Moses Maimonides (1135–1204). In his earlier works (his Arabic commentary to the Mishnah and his *Mishneh Torah* code of Jewish law), he copied the talmudic ruling, adding that “if the precept were really motivated by compassion, then God would have altogether forbidden slaughter.” However, in his more mature philosophical treatise, the *Guide of the Perplexed*, he dismissed that approach as reflecting nothing more than a marginal minority opinion among the talmudic sages, whereas a proper understanding of the Torah does indeed require that all its commandments be placed on a rational or ethical basis (Segal 1991).

The Torah prohibits hybridization of mixed species of fauna and flora, or even ploughing with mixed species or wearing fabrics of mixed wool and linen. Some commentators, such as Rabbi S. R. Hirsch [*Horeb* Ch. 57] ascribe this to a fundamental obligation to “respect the Divine order in God’s creation” in the sense that “You should not interfere with the natural order which you find fixed by God in His world for its ultimate good” (Hirsch 1962, pp. 282–289). If applied consistently, this approach could lead to a complete rejection of genetic modifications of food, though that has generally not been the policy followed by Jewish law. The ban on mixed fabrics has in fact been classified as a “*hok*,” a humanly incomprehensible ritual precept; whereas that on ploughing with an ox and an ass is usually explained as motivated by concern for the animals’ discomfort when they work together at different paces.

Medieval Jewish rationalists like Bahya Ibn Paḳuda and Maimonides insisted that the specific commandments and laws must be understood within a broader spiritual context and that observant Jews should never lose sight of their higher religious purposes. However, their worldviews were usually directed toward a goal of intellectual perfection, and they regarded ethical and moral improvements as means toward that end rather than as ultimate objectives in their own right. Followers of the Lithuanian “Mussar” (moral

discipline) movement led by Rabbi Israel Lipkind Salanter (1810–1883) stressed the primacy of ethical concerns.

The required method of killing animals for both sacrificial and private use, known in Hebrew as *sheḥitah*, was not set out explicitly in the Torah, but was defined in very precise terms in the rabbinic oral tradition. It involved the slashing of the animal’s trachea and esophagus with a very sharp and smooth knife in a single movement. The rabbis supervised the slaughterers very carefully to make sure that there were no nicks in the knife and that the act itself was performed without pauses or inconsistent pressure that could cause pain to the animal. Violators would have their meat declared ritually forbidden for consumption, and the butchers might be disqualified from practicing their profession (Berman 1941, pp. 83–134). It was Maimonides who made the most influential case advocating an ethical or humane rationale for the Jewish procedures of slaughtering animals and fowl for food. In the *Guide* 3:26, in the context of his general argument for the rational basis of the Torah’s laws, Maimonides confronted a problematic passage from the Talmud in which a rabbi stated that it makes no difference to God exactly how an animal is put to death and that the required procedure for slaughter was instituted only to “refine” people and test their obedience. Against this position, Maimonides argued that the Jewish procedure for slaughter embodies the optimal method for achieving a number of desirable ethical objectives. Given that the consumption of meat is essential to the physical well-being of human beings (on this point Maimonides invoked his considerable credentials as a physician), it follows that animals must be killed for food. The sacred law therefore provided a set of rules that would ensure an easy, painless death for the victim. While there might be other ways of achieving this objective, *sheḥitah* has the advantage of being comparatively easy to perform without the need for expensive specialized instruments. It thus provides a reasonable balance between considerations of humaneness and of practicality. If Jewish law had insisted on more elaborate or costly methods, it is unlikely that they would have been widely observed, and

this would have defeated their original purpose (Berman 1941, pp. 432–433).

Medieval rabbinic documents indicate a number of ethical issues that were encountered frequently in connection with the slaughter and sale of meat. For the most part, the issues that arose involved fraud (passing off non-kosher meat as kosher) or the general ethical and moral standards that should be demanded of a butcher, such as whether they could be allowed to follow their trade after being found guilty of a sin or crime. The primary impact of such questions was on the trustworthiness of the butcher's declaration that his meat was kosher. The humane treatment of the animals, albeit a value well established in traditional Jewish ethics (see above), was not considered a central issue in the observance of the dietary rules. The spread of Kabbalah, especially since the sixteenth century, tended to emphasize symbolic and theurgic interpretations of the commandments rather than their social or ethical dimensions. Nevertheless, the kabbalistic doctrine of reincarnation (*gilgul*) promoted the belief, especially in the eastern European Hasidic movement, that proper slaughter might be necessary to allow the errant soul that was reincarnated into the animal's body to be elevated to a higher state of being in its next life (Shmeruk 1965).

Modern Developments

In modern times, Jewish religious authorities began to take a more serious interest in the humane treatment of animals used for food. This was often in response to government initiatives to introduce regulations in that area, beginning in Switzerland in the 1860s, and notwithstanding the fact that such initiatives were frequently motivated by anti-Jewish or anti-semitic agendas (animal rights enactments were among the earliest legislation to be introduced by the German Nazi party). Jewish law also had to confront new realities created by the industrialization of meat processing, as the economic desire for massive output promoted practices that cause severe discomfort and pain to the animals, such as “hoisting and shackling,” force-feeding and restrictive confinement of calves or geese to produce veal or pâté de

foie gras. For example, Canada's “Humane Slaughter of Food Animals Act” of 1959 impelled the local rabbis to investigate humane alternatives to hoisting and shackling, and this led to early adoption of pneumatic restraining mechanisms that were far less traumatic to the animals, but could nonetheless be run at an economically acceptable pace (Klein 1979, p. 93).

As the locus of food processing and distribution shifted away from individual homes and villages and was delegated to impersonal corporations, consumers were increasingly unaware of inadequacies in the standards of humane treatment of the animals. Furthermore, the Jewish insistence on performing the slaughter while the animals are conscious conflicted at times with secular standards that preferred that they be stunned first. The traditional Jewish position has usually been that the procedures for stunning, which might involve a blow to the head or electric shock, cause greater pain than the instantaneous slashing of vital organs required by Jewish law; at any rate, the injuries that are inflicted on the skulls and brains during the stunning can render the animals ritually forbidden. In some cases, attempts were sought to devise halakhically acceptable alternatives for rendering the animals unconscious before the slaughtering.

An instructive example of ethical rethinking in Jewish law is the question of veal. The twentieth century's foremost Orthodox authority on Jewish religious law, Rabbi Moses Feinstein (1895–1986) devoted a responsum to the subject (*Iggerot Moshe E.H.* #92) in which he concluded that the standard methods for producing veal are objectionable for a number of reasons. For one thing, as a consequence of the unnatural conditions in which the calves are bred, the great majority of them are too weak and damaged, especially in their lungs and intestines, to satisfy the health requirements for kosher meat. Ultimately, Rabbi Feinstein declared that the Jewish ethical principle of humane treatment of animals – *ša'ar ba'alei hayyim* – will not tolerate the practice. Even after conceding that legitimate human needs, such as the elimination of hunger or disease or harnessing them for labor, may sometimes override concern for the animals' comfort, the cruelty associated with raising veal calves for financial profit can

hardly be classified as a real “need.” In the present instance, where the calves are fed nutritionally inappropriate foods in order to whiten the red meat and (as Rabbi Feinstein understood it) to create a misleading impression that it is more healthy, the process is essentially fraudulent and ought to be forbidden for that reason alone. While Rabbi Feinstein’s responsum confined itself to very specific issues and did not distinguish clearly between the raising of veal calves and the post facto permissibility of veal, other rabbinic authorities (including those from more liberal Jewish streams such as the Conservative Judaism’s Committee on Law and Standards) have extended his principles to warrant the disqualification of other meats whose methods of production cause undue suffering to the animals (Bleich 2007; Golinkin 1993).

The Impact of Postville

An important milestone in the relationship between Jewish dietary laws and ethics occurred in 2004–2008 with the public disclosure that the Agriprocessors abattoir in Postville, Iowa, the largest kosher meat-packaging plant in America, was guilty of numerous infractions involving mistreatment of the animals, environmental violations, and abusing their workers many of whom were illegal immigrants or children. Jewish religious authorities who might otherwise have maintained a theoretical aloofness from the ethical aspects of kosher food production and marketing were now placed under strong pressure to respond to the moral challenges implicit in the scandal. Previously, avowals of the ethical imperative in food production had been made only by individuals and small groups such as the Jewish Renewal movement (which was advocating the inclusion of ecological criteria for kosher certification in the 1970s), but had minimal impact on the institutional mainstream, especially among the Orthodox communities who were most consistently involved in the observance and enforcement of kosher standards (Waskow 1995; Zamore 2011). Apart from condemnations of the immoral and illegal practices, which were of course shared by Jewish leaders and organizations across the

theological spectrum in North America and in Israel, there has been a call for more consistent institutional policing of ethical standards as dictated by Jewish religious law. Some groups announced plans to issue certificates to any kind of business that satisfied ethical standards for the treatment of their employees (as mandated by Leviticus 19:13, Deuteronomy 24:14, etc. and in the Talmud *Bava Mešia’* Chaps. 6–7, etc.); however, most such programs focused more narrowly on food-related enterprises, taking their cue from the extensive network of agencies that were already in place to certify compliance with the ritual dietary laws. Heretofore, rabbinic bodies usually maintained the traditional distinction between the human-divine and the interpersonal realms, so that a declaration that an item is “kosher” related to such criteria as the ingredients and the vessels in which the food was prepared. Consideration of more indirect factors, such as Sabbath violations or sabbatical year restrictions, has sometimes proven controversial, but has generally been accepted as a legitimate criterion. Now the question is accordingly being posed as to whether kosher certification can also include assurances that labor conditions, humane treatment of animals, honesty, organic standards, and ecological sustainability conform to acceptable halakhic requirements. The type of investigation that is necessary to ascertain compliance in those categories would be much more difficult to monitor and verify than the already complex inspections that are conducted in order to establish the animals’ physiological soundness, the chemical and biological components of the food, etc. (Fishkoff 2010). The research would likely need to be expanded to include financial audits, labor contracts or union policies, information about disposal of waste products, energy consumption, and much more. Such specialized investigations might prove financially prohibitive, and perhaps the most that can be expected is some sort of conditional certification that would be removed in the event of a proven violation.

The flurry of noble intentions and projects that were announced in the immediate wake of the Postville disclosures have been quite slow to translate into concrete actions, but it appears that there can be no turning back at this stage and that

Judaism stands at a momentous turning point in its confrontations with the ethics of food.

Summary

The authoritative sources of Jewish religious tradition contain extensive guidelines for the production and distribution of food within a non-vegetarian ethic. Although there are a number of ethical principles that are implicitly bound with the preparation of food – such as the requirement to set aside portions of the produce for the needy and the prohibitions against causing suffering to animals and against wastefulness – the classification of food as “kosher” has been perceived overwhelmingly as a matter of ritual practice intended to promote discipline and spiritual holiness. Nevertheless, individual Jewish commentators pointed out ethical themes in the dietary laws, such as the implicit exclusion of predatory species, and the fact that the prescribed method of slaughter brings about instantaneous and painless death. Until recently, there were relatively few instances in which rabbis were called upon to invoke ethical factors in connection with food production, such as the problem of milking cows on the Sabbath or the raising of veal calves under conditions of unnatural confinement and unhealthy diet. The scandal of the Agriprocessors kosher abattoir in 2004–2008, with its numerous abuses of animals, workers, and the environment, is leading to a renewed awareness of the ethical factors involved in meat production and how these might be incorporated into the definitions of kosher food.

Introduction

This entry examines the aesthetic and moral thought of Immanuel Kant (1724–1804) with regard to food ethics. Of relevance is three topics: first, why Kant interprets the acts of gluttony and drunkenness as vices; second, how Kant’s moral thought applies to the treatment of nonhuman animals (hereafter “animals”); and third, Kant’s aesthetic arguments on gustatory appreciation. These are discussed in succession below.

Gluttony and Drunkenness as Vices

Beginning with a selective overview of Kant’s moral thought will illuminate why gluttony and drunkenness are interpreted as vices. Fundamental to this overview is Kant’s perception of

humankind as both animal and moral beings. Three predispositions of the human condition are identified accordingly: animality, humanity, and personality. Animality refers to “a physical and merely *mechanical* self-love” (Kant 2009, p. 28): the base impulses humans have as part of their biological nature. Humanity concerns procuring a sense of self-worth in the opinion of others, “to permit no one superiority over oneself” (p. 29). Personality is “the receptivity to respect for the moral law, *as an incentive, sufficient by itself, of the power of choice*” (p. 30). The animality predisposition does not engage with a human’s rational capacities as a moral being, whereas humanity and personality do.

For the (hedonic) utilitarian, moral judgment is bound to the dictates of maximizing pleasure through the consequences of an action. As such, utilitarianism ties morality to the animality predisposition. Kant argues morality should not be understood in this way. This is because utilitarianism reduces humans to heteronomous subjects (Kant 1981, p. 39), “determined to activity through the influence of alien causes” (p. 49). These alien causes are so-called for they lie outside the freedom of will (or one’s reasoning faculties); under the utilitarian framework humans become pleasure-seeking automatons, in thrall to their desires as governed by the laws of nature. For judgments to be considered moral, Kant asserts morality can and should be derived from reason alone. It is only through engaging with one’s rational capacities humans become active

moral agents, rather than being subject to external laws: “Only a rational being has the power to act according to *his conception of laws*, i.e., according to principles” (p. 23). To derive and author one’s own moral principles through reason is to act autonomously, and “thereby [have] a will” (p. 23). Autonomy is thus understood as being tied to a concept of freedom through the rational will acting “independent of any determination by alien causes” (p. 49). Judgments made by the rational will can then be morally evaluated according to its reasoning process and ultimate motive. It follows that only autonomous, rational beings are capable of morality.

The moral law that results from this rational engagement is the categorical imperative, composed of at least three major formulations. The first formulation regards how the rational will should properly act: “I should never act except in such a way that I can also will that my maxim should become a universal law” (p. 14). Through this formulation, motives of selfish, hedonic inclination fail to become suitable moral principles because they cannot be properly universalized without invoking contradiction or paradoxes. Universalizable principles, however, will be consistent with all rational beings given reason is constant. These principles are thus acted upon out of a motive of duty: “the practical necessity of acting according to this principle, i.e., duty, does not rest at all on feelings, impulses, and inclination, but only on the relation of rational beings to one another” (p. 40). To act contrary to this formulation is to revert to pure animality. In following this formulation, humans *qua* moral beings become the authors of their own laws. Moral worth is therefore attributed to acts committed through a motive of duty by autonomous, rational beings abiding by the categorical imperative.

It is this fact, that humans are capable of being the autonomous authors of their own universal laws, which Kant ascribes a special dignity to be respected: “autonomy is the ground of the dignity of human nature and of every rational nature” (p. 41). This is because “nothing can have any worth other than what the law determines. But the legislation itself which determines all worth must

for that very reason have dignity” (p. 41). As such, rational beings ought to be treated as ends in themselves (“objects of respect”) and never merely as a means (p. 36). This gives rise to the second formulation of the categorical imperative: “Act in such a way that you treat humanity, whether in your own person or in the person of another, always at the same time as an end and never simply as a means” (p. 36). Not only then are universal laws simply authored, they are abided by out of respect to all rational beings as ends in themselves. The third formulation expresses this joint rational endeavor. This is the formula of the kingdom of ends: “a systematic union of different rational beings through common laws” (p. 39), in which every rational being in this “kingdom” is perceived and treated as an end.

It has now been shown why Kant does not think morality should be understood as being tied to the animality predisposition. However, it has yet to be shown explicitly what connects Kant’s understanding of morality to the humanity and personality predispositions. These connections are as follows. That humans are autonomous, rational beings leads to their possessing a certain dignity to be respected equally amongst all. This concerns the humanity predisposition, in which no being appears superior to another in moral standing. Equal respect to all rational beings then engenders receptivity to the intrinsic worth of moral law, derived through reason. This fulfills the personality predisposition.

With this theoretical context, it can now be explicated why gluttony and drunkenness are vices. It is reminded that Kant recognizes humans as being both animal and moral beings. Humans ultimately cannot remove their animality, for this predisposition is “bound up with the possibility of human nature” (Kant 2009, p. 23). As such, the animality predisposition must first be appropriately satisfied if humans are to effectively engage with their rational capacities. This essentially involves maintaining appropriate physical sustenance. Consequently, certain special duties are realized when looking after one’s moral health (or humanity). These are “perfect” duties: to maintain “The right of humanity in our own

person” (Kant 1996, p. 32). That these duties are “perfect” indicates a rational being has a constant duty “to himself as an animal being” insofar as their moral health requires it (p. 176). To act otherwise is to violate the second formulation, stripping away one’s dignity as a rational being in the process: recall that the second formulation states a rational being “must in all his actions, whether directed *to himself* or to other rational beings, always be regarded at the same time as an end” (p. 35; my emphasis). Such contrary acts are therefore labeled as vices. Kant lists several acts that would violate the second formulation; among these are gluttony and drunkenness (pp. 180–181).

Kant argues gluttony and drunkenness are vices in a specific way. One might initially suppose these two acts are vices because they impact one’s health in a detrimental manner. In turn, this detriment undermines the ability to properly access one’s rational capacities. Indeed, Kant writes, “Brutish excess in the use of food and drink is misuse of the means of nourishment that restricts or exhausts our capacity to use them intelligently” (p. 180). This is straightforwardly understood with drunkenness; to be drunk is to impair one’s mind to deliberate and act according to a motive of duty. In this state, “A human being who is drunk is like a mere animal, not to be treated as a human being” (p. 180). To be gluttonous, however, is to sink even lower than the base enjoyment drunkenness at least achieves. Gluttony violates the second formulation for it impedes the body through inducing a passive condition, subverting one as an active moral agent. As gluttony, unlike drunkenness, “does not even arouse imagination to an *active* play of representations” a human’s enjoyment of overeating comes close to being on par with “the enjoyment of cattle” (pp. 180–181). On this account, being drunk and/or gluttonous fails to respect oneself as an end; both acts undercut the integrity of the animality predisposition as a means to accessing one’s rational capacities.

However, it is not clear Kant locates the intrinsic moral wrong with gluttony and drunkenness in the consequent damage caused to the physical body (and thereby one’s moral health). Kant writes “the reason for considering this kind of

excess a vice is not the harm or bodily pain (diseases) that a human brings on himself by it” (p. 180). Likewise, the moral wrong does not appear to be in the very acts of eating good food or drinking alcohol either; Kant does not advocate prohibition of alcohol or restricting the enjoyment of food: “Although a banquet is a formal invitation to excess in both food and drink, there is still something in it that aims at a moral end [because] it brings a number of people together for a long time to converse with one another” (p. 181). Instead, it seems the moral wrong in committing the acts of gluttony and drunkenness is identified in the very willingness of the rational individual to choose risking the temporary or permanent loss of their rationality in return for these hedonic states: the rational being’s “insignificance as a *human animal* may not infringe upon his consciousness of his dignity as a *rational human being*” (p. 187). For when one decides to drink excessively or eat too much, selfish inclinations are prioritized ahead of one’s autonomy and therefore one’s freedom. Being cognizant of and still choosing to take this risk is no more than risking one’s very dignity as a rational being.

Kant criticizes those individuals who would choose to take such a risk. For if this risk backfires, the special dignity rationality bestows upon rational beings is destroyed through the very freedom it allows: “if man freely follows his inclinations, he is lower even than the animals [because] he contravenes the essential ends of mankind in his own person, and is acting against himself” (Kant 1997, p. 126). This especially comes to bear due to the addictive nature of good food and alcohol: “They are seductive because, under their influence, people dream for a while that they are happy [. . .]; but dejection and weakness follow and, worst of all, they create a need to use the narcotics again” (Kant 1996, p. 180). That a rational being would choose to risk what confers them moral worth disgraces their humanity predisposition. Indeed, the rational being that does take this risk “cannot demand that others should respect the humanity in him since he has already thrown it away himself” (Kant 1997, p. 147). It is this reason Kant holds most disturbing and thus why gluttony and drunkenness are vices.

Treatment of Nonhuman Animals

The meaning of the term “food” was left ambiguous in the last section. It is not clear whether Kant’s moral thought would reject the eating of some foodstuff over others. Quite clearly cannibalism would be unjustified – to kill and eat one’s fellow rational being would severely violate the categorical imperative in all its formulations. Human meat is therefore off the table. One might wonder, though, whether Kant would say the same about nonhuman animal meat. To answer this query, a deeper understanding of the second formulation of the categorical imperative will be necessary to discern how Kant thought humans should interact with and perceive animals. Recall that all rational beings must be treated as ends in themselves. Kant labels these beings “persons” to emphasize these beings are “not merely subjective ends whose existence as an effect of our actions has a value for us; but such beings are objective ends” (Kant 1981, p. 36). Rational beings, or persons, cannot be substituted for any relative worth. Conversely, nonrational beings are labeled as “things”: “Beings whose existence depends not on our will but on nature” (Kant 1981, p. 35). Things can therefore be treated merely as a means to an end, without moral wrong. Examples of things might include rocks, trees, plants – and animals.

Kant specifically labels animals as things for the following reason: “In animals the inclinations are already determined by subjectively necessitating grounds” (1997, p. 126). This is to say that because animals lack a sufficient rational capacity, they hold no dignity to be respected. It follows that a rational being has no direct moral duty to animals. On first glance, false conclusions of Kant’s thought might be drawn here. If animals are to be perceived and treated as merely a means to an end, this implies humans *qua* moral beings are within their right to use animals in whatever form they wish, without committing any moral harm. Under Kant’s moral framework, one might initially argue factory farms would be deemed acceptable and battery cages for hens permissible. However, these are misgivings because, though animals are things, Kant states rational beings still

have indirect duties towards them. To have an indirect duty is to respect the thing “insofar as they have reference to ourselves” (p. 177). As will be shown, this qualification is enough to discredit the above conclusions transpiring.

Through indirect duties, there are two main reasons given for why one cannot merely treat animals as a means. The first reason regards whether an animal has reference to another rational being. One could not kill and eat a rational being’s beloved pet hen, for instance, because such a principle would disrespect the humanity of the hen’s owner. Note that the reason the hen is not killed and eaten is not through any direct concern for the hen itself. If an animal has no association with a rational being, this first reason does not hold. However, the second reason Kant gives concerns the animal’s reference to the individual acting upon them. The individual rational being should not inflict any kind of deliberate suffering onto an animal because such violent acts violate the individual’s respect to their own humanity. One’s humanity is violated “for it dulls his shared feeling of [the victim’s] suffering and so weakens and gradually uproots a natural predisposition that is very serviceable to morality in one’s relations with other men” (Kant 1996, pp. 192–193). Kant fears a moral spillover will occur, in which “for a person who already displays such cruelty to animals is also no less hardened towards men” (p. 193). A rational being therefore has a direct duty to their own humanity to not be brutal to animals. Consequently, rational beings should practice kindness to other nonrational beings to improve receptivity to the categorical imperative. Again, note that this minimization of suffering does not take place through direct concern for the animal’s well-being; it only takes place through a rational being’s direct duty to their own humanity and rational beings in general.

What follows from this is that the avoidable suffering of animals due to human actions, be it in factory farms or battery cages, is morally impermissible. Such suffering should be minimized as far as possible. Even rational beings that do not directly kill an animal to eat meat should be cognizant of this moral failure; to allow such suffering to continue still reflects a collapse of duty to abide

by the categorical imperative: “Since animals are an analogue of humanity, we observe duties to mankind when we observe them as analogues to this, and thus cultivate our duties to humanity” (Kant 1997, p. 212). This implies, however, that so long as the killing of an animal is committed without reference to a rational being, and done so without painful procedure, this act is morally permissible. This implication is correct; Kant does state, “The human being is authorized to kill animals quickly (without pain)” (p. 193). It therefore remains uncertain how far Kant’s moral thought is able to produce a significant animal ethic through only indirect duties.

Aesthetic Arguments on Gustatory Appreciation

It has been seen above that Kant does not outwardly reject the acts of eating good food and drinking alcohol; neither is the eating of meat prohibited if the animal is killed without reference to a rational being and done so quickly and painlessly. This leaves the last topic of this entry: whether Kant thought there was any aesthetic value in the consumption of food and drink. On Kant’s account, for an object to have aesthetic value – “whether something is beautiful or not” (Kant 1987, p. 44) – one must experience a particular sort of pleasure when encountering the object. The basis of this pleasure “is found in the universal, though subjective, condition of reflective judgments, namely, the purposive harmony of an object (whether a product of nature or of art) with the mutual relation of the cognitive powers (imagination and understanding)” (p. 31). This is to say that all judgments of taste are subjective because one uses imagination “to refer to the presentation to the subject and his feeling of pleasure or displeasure” (p. 44); these pleasures or displeasures are contingent upon one’s experience of the object. For one to make a universal claim about one’s subjective judgment on an object’s aesthetic value, this judgment “lays claim to everyone’s assent” (p. 64). An object can only be said to have aesthetic value when universal agreement on a subjective judgment is

achieved. As we will see, Kant argues gustatory appreciation lacks aesthetic value.

More needs to be said on what particular sort of pleasure one must experience if universal assent on a subjective claim is to be achieved. This will identify why Kant reaches the conclusion he does on the aesthetic value of gustatory appreciation. The sort of pleasure one needs to experience to make universal subjective claims is one of disinterest. A disinterested pleasure refers only to “the subjective purposiveness in the presentation of an object, without any purpose” (p. 66). This is to say, given an object (like a painting) provides enough material for the imagination to fully engage with over a period of sustained contemplation, one constructs a personal interpretation (or cognitive understanding) as to the purpose of the object (why certain brushstrokes were used, or why a figure’s clothing is colored in an unusual way). A disinterested pleasure is thus derived through “the reflective power of judgment” (p. 30) in harmonizing one’s imaginative “*free play*” and the cognitive understanding of the purpose of an object. Note, therefore, that a disinterested pleasure of this purpose only appreciates the object’s intrinsic presentation. This is opposed to taking an interested pleasure in the object for an instrumental reason (that a loved one painted the picture, for instance).

This “reflective power of judgment” is necessary to attain the support of other rational beings in arguing that one’s subjective claim is universal. Recall in the overview of Kant’s moral thought that reason is constant among all rational beings. This assumption is vital for Kant’s aesthetic theory. When one wishes to make a universal claim about a subjective judgment, “he requires the same liking from others; he then judges not just for himself but for everyone” (p. 55). For if one determines through reflection that their subjective judgment is compelling, “we are conscious that this subjective relation suitable for cognition must hold just as much for everyone” (p. 62). An object that passes this test of achieving aesthetic value is considered “beautiful.” As such, aesthetic judgments do not constitute private subjective claims that are “agreeable” (what merely gratifies us as individuals) (p. 52). Agreeable judgments

lack aesthetic value because they do not include a human's rational capacity for reflection, only a personal "interest of inclination" (p. 52).

Enjoyment of food and drink, Kant argues, does not get past this initial personal experience to reach a potentially universal subjective judgment – gustatory appreciation is therefore only agreeable. The reason Kant gives is that one's enjoyment of food and drink is only based on one's appetite. As such, the subsequent judgments on food and drink that are made cannot be considered valid because they are dependent on one's hunger. Kant invokes the adage, "Hunger is the best sauce; and to people with a healthy appetite anything is tasty provided it is edible" (p. 52). Consequently, gustatory appreciation is constrained by interests of inclination, and thus no disinterested pleasure is gained.

Despite these above comments, Kant does concede there may be one possible way to overcome this constraint. For a person who has contented their hunger may be able to make potential universal subjective claims on the next meal presented to them: "Only when their need has been satisfied can we tell who in a multitude of people has taste and who does not" (p. 52). This does not imply a person must be already overfed. Remember that one who indulges in gluttony enters into a passive state that hinders one's capacity to reason. Instead, as Kant chooses his words, this person's hunger must just be "satisfied." Maybe an aesthetic encounter could be made if this qualification is fulfilled.

However, Kant does not think this qualification can be attained. First, this qualification is wrought with issues of conceptualization: ambiguities abound as to what a satisfied state of appetite actually is. Yet even if it is supposed no ambiguity existed, this is a qualification that would still appear impossible to achieve when one recalls Kant's procedure for how to claim a subjective judgment as universal. A potential universal subjective judgment comes from a disinterested pleasure derived through a period of contemplation that harmonizes one's imagination and cognitive understanding of an object. Kant argues that when food or drink is consumed a disinterested pleasure cannot occur because one only has immediate

sensation and pleasure of these objects. This immediacy does not offer extended engagement with how pleasurable the consumption was, given the food and drink being consumed is swallowed almost straight away. No contemplation can therefore occur; if this pleasure of gustatory appreciation always comes before the contemplation (and not as a result of it), a disinterested pleasure cannot be generated. Instead, Kant writes that this kind of "interested" pleasure "would be none other than mere agreeableness in the sensation, so that by its very nature it could have only private validity, because it would depend directly on the presentation by which the object is *given*" (p. 61). Gustatory appreciation can therefore never become more than a private interested pleasure.

Summary

This entry has hoped to display three things: first, the major reason Kant interprets gluttony and drunkenness as vices is due to a rational being risking their humanity in exchange for these two hedonic states; second, that rational beings only have indirect duties to animals under Kant's moral framework; and third, Kant's argument that gustatory appreciation cannot achieve disinterested pleasure means the consumption of food and drink cannot have aesthetic value.

Introduction

In *Powers of Horror*, Julia Kristeva discusses food prohibitions in the context of developing a general theory of abjection. There, she defines the abject as what defies categorization and thereby inspires both horror and fascination. As she describes it, abjection is an essential part of psychic development and necessary for weaning a child from its dependence on its mother's body. She also argues that abjection is part of the process of becoming a human being. If on the level of the individual abjection is necessary for separating from the maternal body, on the level of the social, abjection is necessary for separating from the animal. Both of these separations involve eating and prohibitions against eating. In terms of the maternal body, the infant is weaned off of breast milk. In terms of the social, the infant learns that it is not an animal and therefore must abstain from incestuous, cannibalistic, or murderous urges. In an important sense, one becomes human by eating other animals rather than one's kin. This distinction between kin and food is elemental in how an individual conceives of herself in relation to others and the world, particularly the world of nonhuman animals.

The Notion of Abjection

Kristeva's *Powers of Horror* analyzes powerful fantasies of eating and devouring associated with both animals and women, particularly mothers. The first half of *Powers of Horror*, which sets out the theory of abjection, could be read as an account of the essential link between animal and mother in the constitution of the human psyche. As Kristeva describes it, abjection is the result of the return of repressed ambiguity or ambivalence inherent in the "fragile" boundaries between maternal body and infant on the personal level and animals and human on the social level. The abject, so to speak, is neither fish nor fowl; but rather, it is the in-between that resists categorization. This is why it provokes both fear and fascination.

The Oral Stage in Psychic Development

On the level of the infant, these fears revolve around the oral phase with biting, eating, and devouring. Kristeva argues that fear, especially in children who have animal phobias, hides an aggression, which at the earliest stages is an oral aggression related to both food and speech (1980, p. 39). The child feels aggression in response to its fear both of the loss of maternal satisfaction and of paternal prohibition against its closeness with the maternal body. She argues that the child responds to both deprivation and prohibition with aggressive impulses, which in the case of the maternal body may literally include the urge to bite or devour to incorporate the maternal body in order to hold on to it (cf. 1980, p. 39). In the case of animal phobia, the child's own aggressive instincts are projected onto something outside of itself, an animal, as a shield not only against the deprivation and prohibition exercised toward it by its parents but also against its own violent impulses, most particularly the urges to bite and eat. At this stage, these impulses revolve around incorporation as an attempt to devour and thereby possess the parental (not yet) love object.

The Good and the Bad Breast

For Kristeva, there is an inherent connection between eating and other forms of assimilation, including the assimilation of love and of language. In the beginning, all of these forms of assimilation come through the mouth. For the infant, the mouth is the first center of bodily cathexis associated with pleasure, deprivation, and language acquisition. Words, like breast milk and its food, pass through its mouth. Kristeva interprets the phobic's fantasies of being bitten, eaten, or devoured by a scary animal as a projection of its own aggressive drives, particularly the urge to bite, eat, or devour the maternal body. Following Melanie Klein, Kristeva identifies the infant's earliest desires to bite, eat, or devour in relation to the mother rather than the father; originally, the infant's ambivalence is directed toward her. In Kleinian terminology, the mother's breast is split into the good and the bad breast. The bad breast threatens to turn on the infant and bite or devour him: the maternal breast bites back. Kristeva extends this Kleinian thesis with her theory of the abject mother, who appears as both fascinating and threatening to her child.

Phobia, then, represents the failure of introjection of what is incorporated through the mouth, both maternal breast and paternal words (1980, p. 40). The precocious child does not yet have the linguistic or symbolic competence to properly displace the thing by substituting words, so it displaces by inverting its own impulses to bite and eat onto a telegraphic symbol like the phobic animal. This child may have a facility with, and fascination for, words, but its logorrhea does not effectively stop up the empty mouth deprived of the maternal breast.

Abjection and the Maternal Body

For Kristeva, fear of animals is correlative to fear of maternity. On the level of the social, this power is the mother's generative power (1980, p. 77); on the level of the individual, this power is the mother's authority over the infant's body and its satisfaction. Both collectively and individually,

infants depend upon the maternal body (and animals) for continued life, especially nourishment; and this dependence is repressed through a process of abjection in order for the group or individual to assert its independence and fortify the boundaries of its identity. Kristeva interprets prohibitions against incest and contact with mothers or women, particularly during menses – symbol of women’s fertility and generative powers – as attempts to regulate their power, what she calls “a loathing of defilement as protection against the poorly controlled power of mothers” (1980, p. 77).

Prohibitions Against Cannibalism and Incest

Relying on anthropological literature, Kristeva maintains that in cultures where population growth is needed for survival, prohibitions against contact with the maternal body, namely, incest and cannibalism, are relaxed (1980, p. 78). These anthropological accounts lead her to ask “Is that parallel [between concerns for over –population and prohibitions] sufficient to suggest that defilement reveals, at the same time as an attempt to throttle matrilineality, an attempt at separating the speaking being from his body in order that the latter accede to the status of clean and proper body, that is to say, non-assimilable, uneatable, abject?” (1980, p. 78). She goes on to suggest that fear of the generative power of the mother not only makes her body abject and uneatable but also makes all bodies abject and uneatable. She says “I give up cannibalism because abjection (of the mother) leads me toward respect for the body of the other, my fellow man, my brother” (1980, p. 79; parentheses in the original).

The body becomes inedible, not literal flesh and blood that like animals’ can be consumed, but rather metaphorical flesh and blood, which is to say, kin – fellow man, brother. In other words, giving up the literal consumption of flesh and blood produces and is produced by the metaphorical notion of flesh and blood as kinship. Humans don’t eat their kin. In terms of animals, the circular logic runs as follows: if humans eat animals, they

are not kin; animals aren’t kin, so humans eat them. Because their flesh and blood is literally consumed, they are not metaphorical flesh and blood and vice versa; because they are not metaphorical flesh and blood, they are literal flesh and blood in terms of what humans eat.

Kinship by Marriage or Meals?

Given Kristeva’s analysis of the structural relation between the mother and the animal in the process of abjection and identity formation, it’s important to ask why the taboo against eating the abject maternal body does not also apply to eating the abject animal body. We might ask why the taboo against eating the abject maternal body does not also apply to eating the abject animal body. On Kristeva’s analysis, the social struggle against the abject is a battle of the sexes over whether paternal or maternal power will triumph; it is a battle between patriarchal and matriarchal social formations. Behind these struggles, however, lay the animals. Even while discussing the power struggle between masculine and feminine or paternal and maternal, Kristeva returns to the animal. She asks whether food loathing or prohibitions against certain foods, particularly animal flesh and animal products, are a matter of marriage or of meals.

Following this line of thought, which comes from the anthropologist Célestin Bouglé, and combining it with the theories of anthropologists Louis Dumont and Mary Douglas, Kristeva argues that loathing or revulsion must be explained in terms of an opposition between pure and impure, which is imposed upon or displaces sexual difference. The opposition between pure and impure allows for the substitution of rituals of purification for sacrifice. Both rituals of sacrifice and rituals of purification, however, revolve around killing and eating animals. Kristeva traces the origins of religion, particularly religious taboos; and she finds the mother and maternal body behind all such taboos. In the transition from rituals of sacrifice to rituals of purification, one thing remains the same, the abjection of the maternal body.

Biblical Food Prohibitions

The role of the maternal body in relation to the animal is particularly poignant in Kristeva's analysis of what she calls the "semiotics of biblical abomination" or the food prohibitions of the Old Testament (see 1980, Chap. 4). She argues that fear of the maternal body and its generative power and its authority over the bodily functions of children gives rise to food taboos involving mixing her body (or its symbolic equivalents) with the bodies of her children (or their symbolic equivalents). On the symbolic and imaginary levels, she interprets these food prohibitions as again revolving around the abjection of the maternal body. Literally, however, this abjection is played out on the bodies of animals and regulations about what parts of those creatures can and cannot be eaten and how. In this regard, all animal bodies become symbols for the maternal body and its relation to the bodies of children (which is to say the maternal body of all, since all are born from a maternal body). Animal bodies become symbols for human bodies; and both our rituals of animal sacrifice and of purification involving eating only certain animals or animal parts harken back to the maternal bond.

Food Prohibitions and the Maternal Body

Although Kristeva identifies food prohibitions with border issues that relate humans to non-human animals, her analysis continually brings those issues back to the maternal body. She says: "When food appears as a polluting object, it does so as oral object only to the extent that orality signifies a boundary of the self's clean and proper body. Food becomes abject only if it is a border between two distinct entities or territories. A boundary between nature and culture, between the human and the non-human" (1980, p. 75). This passage suggests that the boundary with nonhuman animals "pollutes" the clean and proper borders of the human. On Kristeva's analysis, however, this pollution turns out to be just another form of maternal contaminant. Her thesis

is that "biblical impurity is permeated with the tradition of defilement; in that sense, it *points to* but does not *signify* an autonomous force that *can* be threatening for divine agency. Such a force is rooted historically (in the history of religions) and subjectively (in the structuration of the subject's identity), in the cathexis of maternal function – mother, women, reproduction" (1980, p. 91). She argues that dietary prohibitions are aimed at the mother as the first source of nourishment and milk. These taboos are attempts to fortify precarious boundaries between the maternal body and the social and individual subject insofar as they are directed toward "intermixture, erasing of differences, threat to identity" (1980, p. 101). Biblical food prohibitions are aimed at separation and distinctions that avoid the ambiguity and mixing threatened by the maternal body. All food prohibitions, then, according to Kristeva, are symbolic regulations of the power of the maternal body.

Thou Shalt Not Seethe a Kid in His Mother's Milk

For example, she maintains that the biblical command "Thou shalt not seethe a kid in his mother's milk" is a metaphorical prohibition against incest between mother and child symbolized by mixing its flesh with her milk (1980, p. 105). She concludes that biblical dietary prohibitions are "based upon the prohibition of incest" (1980, p. 105). All food taboos involving animals, on the symbolic level, are really prohibitions against contact with the maternal body. Kristeva even interprets the Eucharist in terms of the maternal body. Unlike Sigmund Freud who in *Totem and Taboo* describes the Eucharist as another ritualistic repetition of the totemic celebration of eating the father, Kristeva sees it as both a repetition and disavowal of the primal "object" of the urge to devour, the mother. She suggests that cannibalistic urges to eat the body of another are always disguised (or not so disguised) wishes to eat the mother (Freud 1913). On her account, every body recalls the maternal body, the first body encountered by the infant. The Eucharist brings

together food and body in a ritualistic way that harkens back to cannibalism, symbolically repeating it as a way of preventing actual eating of bodies – except, as discussed earlier, the bodies of animals. Kristeva maintains that by bringing together body and bread, the Eucharist tames cannibalism: “By surreptitiously mingling the theme of ‘devouring’ with that of ‘satiating’, that narrative [the Eucharist] is a way of taming cannibalism. It invites a removal of guilt from the archaic relation to the first pre-object (ab-ject) of need: the mother” (1980, p. 118). It is noteworthy that in this passage, Kristeva talks of “taming” cannibalism as if it is an animal instinct that must be domesticated. Furthermore, she identifies both the urge to devour and satiation with the maternal body by insisting that the Eucharist is a purification ritual aimed at curbing and regulating incestuous and cannibalistic desires for the mother and the maternal body.

The Substitution of Mother for Animal

In her analysis of biblical dietary restrictions, she discusses at length taboos on various animals and animal parts, but continually insists that these animals are stand-ins for the mother, much like Sigmund Freud who insists that the animals in animal phobias are representatives for the father. The process that Kristeva describes, however, is the metonymic slippage from milk and blood to maternal body rather than the metaphorical substitution of horse or wolf for paternal threats. Kristeva is concerned to distinguish the process of substitution or sacrifice identified by Freud in *Totem and Taboo* from the process of ritual purification involving dietary restrictions rather than killing and eating per se. In other words, dietary restrictions prevent the kind of murderous sacrifice of the primal horde whereby the animal becomes the father and vice versa. What Kristeva does not acknowledge is that animals are still killed and eaten even when purification rituals regulate that activity. The difference is one of emphasis. In purification rituals, the killing of animals is no longer a necessary part of the ritual (with some exceptions, e.g., Jewish kosher

regulations on the bleeding of animals, which Kristeva interprets as again signaling the threat of blood, a metonym for menstrual blood). In all cases, however, animals are killed; only now their killing is not part of a ritual sacrifice but a regular part of domestic culinary practices, which involve various restrictions focused on how animal flesh is prepared. In other words, the killing of animals becomes domesticated.

Ritualistic Feasts and Dietary Prohibitions Prevent Violence

Kristeva sees the progression from ritual sacrifice to rituals of purification as a move away from violence and toward more sublimatory and therefore more humane forms of regulation; her analysis suggests that ritual sacrifice glorifies the violence of killing, while rituals of purification sublimate it. Yet, contra Kristeva, it could be argued that rituals of purification merely domesticate the killing of animals and allow for a radical disavowal of their slaughter to the point of creating factory farms, where mass killing is hidden away from view rather than ritualized but extremely limited killing celebrated as animal sacrifice. Animals are no longer sacrificed because neither their lives nor their deaths have the symbolic value they did prior to domestication. Within psychoanalytic theory, their only symbolic value is either as a substitute for the father ala Freud or a stand-in for the mother ala Kristeva.

The Psychoanalytic Sacrifice of Animals for the Sake of Human Kinship

Moreover, the psychoanalytic domestication of animals itself forecloses not only the possibility of their wildness but also the possibility of their kinship with humans. They cannot replace mothers or father or sisters or brothers, but rather they must represent them or stand in for them. They must be either sacrificed instead of them – that is to say killed in their stead. Or, they must be regulated as a means of regulating ourselves. In

either case, their value is defined entirely in terms of human relations and human exchange. Whether sacrificed or regulated, animals are killed or exchanged so that human society and human kinship is possible; and all of these accounts are based on, or presuppose, killing and eating animals. In this case, humans are not what they eat, and eating animals proves that they are not like them. Rather, humans become fathers, mothers, sisters, and brothers on the basis of killing and eating animals. Symbolically, they bind individuals together as kin through the flesh and blood of their bodies and, at the same time, reassure that if humans can eat them, then humans are not animals. Literally, their death as animals makes it possible to live as humans.

Eating Separates Humans from God

Kristeva also describes the distinction between man and God as a dietary distinction. Man is not God because, unlike God, he/she is prohibited from eating certain foods. For example, in Genesis, God expels Adam and Eve from the Garden of Eden for eating from the tree of knowledge, but he does so before they can eat from the tree of life, which would make them immortal (cf. Kristeva 1980, p. 95). Kristeva points out that Adam's temptation is both a feminine and animal temptation – Eve is tempted by the serpent, and Adam is tempted by Eve to eat the forbidden fruit. Kristeva interprets Genesis as reserving dominion over living beings for God and giving man the right to eat animals only after the flood and only then as an acknowledgment of his/her essential evil (1980, p. 96). At this point, temptations of the flesh become associated with both women and food, particularly meat eating. Temptations of the flesh can be interpreted as temptations arising from the flesh, from our so-called animal nature, or as temptations for flesh, as in the temptation to get “a piece of tail” either in the sense of women's flesh or in the sense of a rump roast. Kristeva reads this urge to kill and eat flesh as recognition of the death drive in its most primordial form, as the urge to devour (1980, p. 96). The prohibition against murder is no longer extended to killing and eating

animals, but rather becomes displaced onto dietary prohibitions that prohibit eating carnivorous animals; man can eat only herbivorous animals and cannot eat or assimilate-incorporate rapacious animals or predatory animals that kill. This murderous nature is displaced onto the animals that one is not allowed to consume (cf. Kristeva 1980, p. 98).

Violence Toward Women and Toward Animals

Although her analysis of the death drive and the urge to devour in relation to killing and eating animals is an explicit acknowledgment of violence done to animals in order to shore up the boundaries of the notion of the human and of ourselves as nonanimals, again Kristeva presents it as more evidence that animals are stand-ins for the maternal body. Immediately following her discussion of the death drive in relation to devouring animals, she claims that biblical dietary prohibitions are paralleled and founded in “the abomination provoked by the fertilizable or fertile feminine body (menses, childbirth)” (1980, p. 100). Kristeva's analysis not only makes explicit that abjection of the feminine and maternal body upon which the Western imaginary thrives and upon which man defines himself as clean and proper, but also it points to the inherent connection within this imaginary of animals and women, particularly mothers. What animals and mothers supposedly share is their connection to nature, and, as Kristeva says, “the body must bear no trace of its debt to nature: it must be clean and proper in order to be fully symbolic” (1980, p. 102).

To acknowledge this debt, then, is not only to break the incest taboo by speaking of connectedness to the maternal (animal) body but also to stage the return of the repressed maternal, animal, and body. As many feminists have pointed out, within the Western imaginary, man constitutes himself as properly man against both the feminine and the animal. Kristeva's analysis makes a crucial contribution to psychoanalysis by revealing man's indebtedness and subsequent disavowal of

both. She does so in part by complicating the maternal function, which she imbues with speech, law, and authority, attributes traditionally reserved for the paternal function and required for autonomy from the maternal body. Yet, what Kristeva's theory of abjection itself disavows, even while describing, is an indebtedness to animals, who metaphorically and literally nourish an individual's sense of self as human and as kin. The very notions of maternity or paternity, mother or father, that drive psychoanalytic theory are based on the displacement or condensation of these figures and animals. Whether it is Freud's father totem phobia or Kristeva's mother meal abject, the slippage between animals – specifically dead ones – and one's closest and most influential kin is formative of both social identity and individual identity. Moreover, on this account, nonviolence toward other human animals is bought at the expense of violence toward nonhuman animals.

Summary

Whether it is Freud's father totem phobia or Kristeva's mother meal abject, the slippage

between animals – specifically dead ones – and one's closest and most influential kin is formative of both social identity and individual identity. Moreover, on this account, nonviolence toward other human animals is bought at the expense of violence toward nonhuman animals.

La Via Campesina

William Schanbacher

Department of Religious Studies, College of Arts and Sciences, University of South Florida, Tampa, FL, USA

Introduction

The global food system illuminates one dimension of the massive socioeconomic inequality that characterizes the world today. In a global population of over seven billion people, roughly 795 million people remain undernourished as of 2014–2016, according to the Food and Agriculture Organization's (FAO) estimates (FAO 2015: 8). Despite progress made over the last 20–30 years, inequalities in the global food and agricultural system have generated heated debate about policy solutions as well as galvanized diverse sectors of society – whether national governments, nongovernmental organizations, multilateral institutions, and grass-roots social justice movements, among many more – to challenge the current state of the system.

It is in this context that La Vía Campesina, one of the world's most powerful social justice movements dedicated to food and agricultural justice, emerged in 1993. Translated as the “peasants way” or “peasants road” (Desmarais 2007: 8), the organization is:

an international movement embracing organizations of peasants, small and medium-scale farmers, rural women, farm workers and indigenous agrarian communities in Asia, the Americas, Europe and Africa. (Desmarais 2008: 138)

According to La Vía Campesina, as of 2011, the organization consisted of 164 local and national organizations in 73 countries (La Vía Campesina 2011). It fights against the industrial and neoliberal model of agricultural development and the consolidation of corporate control over the global food system and “provides opportunities for peasants to articulate a coherent set of demands in the international arena” (Desmarais 2008: 138). The following analysis of La Vía Campesina begins with situating it in its historical context. Following the important essay by María Elena Martínez-Torres and Peter Rosset (2010), the growth and evolution of La Vía Campesina is differentiated into five phases, each demarcated by pivotal theoretical changes or watershed events that have helped shaped what the organization is today. Finally, in conclusion, the essay will highlight its successes as well as point out some particularly significant challenges that may lie ahead.

Historical Phases of Transnational Social Movements and La Vía Campesina

Phase 1

Scholars María Elena Martínez-Torres and Peter Rosset trace the historical development of

transnational social movements, identifying five pivotal periods of transition and evolution of La Vía Campesina. From the early period of the 1980s–1992, we witnessed the transformation of Third World nation-states alongside certain challenges encountered by rural populations and small-scale farmers on the whole. During this period many nation-states had “a mixed attitude toward peasant food producers in that they wanted to support them to feed urban workers, but do so with low crop prices” (Martínez-Torres and Rosset 2010: 153). This state-centered “developmentalist” approach, as it was called, essentially maintained rural poverty and did nothing for the plight of rural peoples.

Moreover, this developmentalist phase occurred during the time when the aftershocks of the structural adjustment programs (SAPs) of the 1970s–1980s were first being felt throughout Latin America, not coincidentally the eventual birthplace of La Vía Campesina. Promoted by multilateral organizations such as the World Bank and the International Monetary Fund (IMF), alongside trade agreements orchestrated by the World Trade Organization (WTO) and the North American Free Trade Agreement (NAFTA), SAPs encouraged neoliberal economic principles that advocated general policies of trade liberalization, privatization, deregulation, and the opening of markets (Schanbacher 2010). The global socioeconomic changes initiated by these multilateral organizations altered peasant groups and communities and ultimately forced them to change strategies and modes of resistance in the face of growing instabilities in the global food and agriculture system. Most notably, the need to distance themselves from urban interests diverse social interest groups created a new political platform that would ultimately emerge as La Vía Campesina and its member organizations (Martínez-Torres and Rosset 2010: 152).

La Vía Campesina and Food Sovereignty

Phase 2

From 1992–1999, the second phase of peasant resistance was marked by a concerted effort to

assert greater autonomy with respect to decision-making processes within coalescing peasant movements. In doing so, La Vía Campesina fought to separate itself from nongovernmental organizations (NGOs) and refused to grant membership to organizations, foundations, and aid agencies that were “not true, grassroots-based organizations” (Martínez-Torres and Rosset 2010: 158). By doing so, La Vía Campesina recognized the need for a certain degree of autonomy. During this phase, La Vía Campesina coined its official name and demanded to:

take their seat at the table in their own name, pushing aside NGOs and others who had previously ‘spoken on behalf’ of rural peoples, with the clear message that, ‘we are here and we can speak for ourselves’. (Martínez-Torres and Rosset 2010: 158)

The need to distance themselves from outside organizations was due in part to the structure of NGOs. Usually, NGOs are accountable to their Board of Trustees, who in turn has final control over which strategies and projects to endorse. Often projects are project based and do not seek broader political changes or restructuring that would radically change the status quo. In 1996 the demands of La Vía Campesina were officially avowed at the Second Conference in Tlaxcala, Mexico, where it declared itself “a movement, not just a mere ‘coordination,’” solidified its regional connections, included gender issues as central components of the movement, and continued to develop the concept of food sovereignty (Martínez-Torres and Rosset 2010: 159).

Officially coined in 1996 by La Vía Campesina, the term food sovereignty has grown to be perhaps the most powerful movement or concept associated with issues of food, agricultural and land reform, human rights, and biodiversity, among many more. Reflecting on the concept of food sovereignty, Annette Desmarais accurately captures its multidimensionality, noting that people call it an “‘idea,’ ‘concept,’ and framework”; others prefer to call it a “‘mobilizing tactic,’ a ‘political project,’ a ‘campaign,’ and a ‘movement’; still others refer to it as a ‘process’ a ‘vision,’ and a ‘living organism’” (Desmarais 2014: 3).

This diversity of meanings illustrates the complexity of food sovereignty yet also captures many

integral components of transnational social justice movements. In order to coalesce a wide variety of peasant and small-scale farmer voices, with their language differences, occasional conflicts of opinion, sometimes-competing goals and strategies, and so forth, it was important that the concept was open to many interpretations and usages. Navigating different political realities – depending on region, country, or village – food sovereignty needed to be a malleable concept capable of addressing context-specific situations.

However, despite its diversity, and echoing La Via Campesina's demand that member organizations meet the minimal threshold of holding core values, all member organizations supported and continue to uphold food sovereignty's guiding principles. Although the definition of food sovereignty has evolved over time, one of its early iterations captures its core values:

Food sovereignty is the right of peoples to define their own food and agriculture; to protect and regulate domestic agricultural production and trade in order to achieve sustainable development objectives; to determine the extent to which they want to be self-reliant; to restrict the dumping of products in their markets; and to provide local fisheries-based communities the priority in managing the use and of the rights to aquatic resources. Food sovereignty does not negate trade, but rather, it promotes the formation of trade policies and practices that serve the rights of peoples to safe, healthy and ecologically sustainable production. (Patel 2010: 189)

Notice, this definition aims for multiple goals and requires essential demands for achieving a more just global food system. First, the definition demands that people and their domestic governments control their agricultural production and trade. This is a direct challenge to the WTO's foundational philosophy of trade liberalization, which relegates these decisions to the market. However, as the definition goes on to further note, food sovereignty is not patently against free trade. Rather, food sovereignty is against unfair trade policies that protect affluent countries, privilege massive corporations, and promote the dumping of products into developing countries. Privileging affluent countries and ultimately contributing to their large corporations essentially removes power from of the control of much of

the worlds' peasant and small-scale farmers, in turn destroying traditional farmer livelihoods, and ultimately contributes to mass migrations into urban slums, all in the name of corporate profits for a select few businesses. Furthermore, dumping refers to the process by which powerful nations subsidize their agricultural industries which, in turn, produces surpluses for export. Dumping subsidized products into developing economies eliminates the possibility of, and hope for, competition by local farmers, often resulting in the destruction of small-scale farm operations.

Second, food sovereignty demands the power to determine the local community's production of safe, healthy, and ecologically sustainable foods. This is perhaps one of the greatest practical challenges today for transnational food-justice movements, as the corporate control over the global food system is increasingly consolidating. For instance, as of 2013, the world's top ten corporations controlled over 75 % of the commercial seed market, the top ten corporations controlled 41 % of the global fertilizer market, the top six corporations held 76 % of the global agrochemical market, the top seven firms controlled 72 % of the animal pharmaceuticals market, and the top four global companies dominated 97 % of poultry genetics R&D (ETC Group 2013). And, finally, the "same six multinational firms (Monsanto, DuPont, Syngenta, Bayer, Dow, and BASF) controlled 75 % of all private sector plant breeding research, 60 % of the commercial seed market (100 % of the transgenic seed market) and 76 % of global agrochemical sales" (ETC Group 2013). As corporations exercise greater power through both horizontal and vertical integration of food and agriculture chains, peasant and small-scale farmers are squeezed to the point of extinction.

Third, and perhaps the most controversial, is the demand that food be considered a human right. Discourse on human rights is vast and beyond the scope of this article, yet food sovereignty contends that, as a basic human necessity, food should be categorized as a human right. Article 11 of the United Nations' International Covenant on Economic, Social and Cultural Rights (ICESCR) supports the food sovereignty demand that all peoples

have a right to an adequate standard of living, including adequate food. Despite the rights outlined in Article 11, countries such as the United States have failed to agree to the basic language of the article. Instead they propose that all people have the *opportunity* to secure basic needs such as food, shelter, clothing, and health care (Schanbacher 2010: 31). The essential point in the food sovereignty demand for the human right to food is that it is a basic human need and should not be contextualized in the language of an opportunity to food, but rather ensured by mechanisms of global society (whether by domestic governments, NGOs, multinational organizations, aid agencies, and so forth). Finally, food should be understood as more than simply an isolated, impersonal commodity and rather as a cultural artifact that ties generations, communities, and livelihoods together.

Phase 3

Phase three (2000–2003) began with the Third International Conference in Bangalore, India, whereupon La Vía Campesina sought to build “alliances with other actors to pressure institutions like the World Bank, the WTO, IMF and United Nations” (Martínez-Torres and Rosset 2010: 161). During this period, La Vía Campesina ramped up efforts to fight against persistent trade liberalization policies of the WTO and the NAFTA. Furthermore, corporate consolidation continued to intensify, resulting in the growing destruction of rural livelihoods. As discussed above, the corporate consolidation of global markets facilitated by the WTO also involved the patenting of living organisms, including genetically modified seeds.

This is especially problematic considering farmers have been cultivating and trading seeds for millennia. As activist and scholar Vandana Shiva notes, “Seeds are a gift of nature, past generations, and diverse cultures,” the “first link in the food chains, and the repository of life’s future evolution” (Shiva 2007: 77). The consolidation of seed markets was facilitated in part by the implementation of the Trade-Related Aspects of Intellectual Property Rights (enshrined in the WTO), which governs rules regarding patents, trademarks, and copyrights. Ostensibly, the

intention of TRIPS was to provide a platform for countries (especially developing countries) to settle unfair trade disputes. However, as it has played out, the TRIPS agreement also extends patenting rights for living resources including genes, cells, and plants – all living organisms that activists argue should not be the private property of corporations. Instead, these are living, breathing organisms that should not simply be bought and sold, but rather are common resources that should be protected and available to all of humanity.

Finally, corporations operate by what could be called the profit ethic, a moral system that is driven by the corporations’ own internal goals, which often focus on shareholders rather than stakeholders (i.e., global farmers) and on externalizing environmental, health, or sustainability costs. To put it in the form of a question: where did we get the idea that common resources such as seeds, plants, water, and air could be owned as private property? Some economic proposals such as cap and trade address this issue but fail to recognize the fundamental problem with conceptualizing these resources as traditional commodities. Instead, they are resources necessary for the survival of all of humanity and nature and thus are markedly different than an iPhone or T-model Ford. The culmination of these opposing ethical perspectives came in Cancun, Mexico, during the 2003 meeting of the WTO. Here, on September 10, in a dramatic and tragic display of protest against the harmful effects of WTO trade policies, Korean farmer Lee Kyung Hae climbed a police barricade garnishing a knife and a sign reading “WTO kills farmers.” Lee attended the protests to march in solidarity with the Mexican farmers and, in the ultimate act of sacrifice, stabbed himself in the heart to death. This act of resistance illustrates that death for these peasant farmers is “in fact a recurring theme, and reality, of the peasant struggle in Latin America and the world. It is both the deaths from hunger-related illnesses in impoverished areas and the deaths from the on-going criminalization and repression of peasant struggles” (Martínez-Torres and Rosset 2010: 163).

During this period and in solidifying alliances, La Vía Campesina became a stronger oppositional

force as well as strengthened its internal goals. Perhaps most significantly, the Third International Conference in Bangalore intensified efforts to accomplish gender parity and ultimately succeeded in adopting the requirement that equal gender representation occur at all levels of La Via Campesina decision-making processes and events. The struggle of women's participation in La Via Campesina has been a difficult process but has culminated in some incredible successes.

In the Sixth International Conference in Jakarta, Indonesia, in 2013 the women of La Via Campesina reaffirmed their integral role in the movement. They reiterated their goals of building a universal and sociopolitical movement in "defense of peasant agriculture, food sovereignty and the struggle for the land, territories justice, equality and the dignity of peasant women and men" (La Via Campesina 2013). The women highlighted their key role in successfully promoting and enacting political struggles to fight for the defense of "Mother Earth," violence, and discrimination and forced displacements, among many other things. Of crucial importance was the right to access to land. As the Women's Manifesto declares, "To us, the peasant and indigenous women, the land is more than a means of production. It is a space of life, culture, identity, and emotional and spiritual environment. Because of that it is not a commodity, but a fundamental component of life, which is accessed by rights that are inalienable" (La Via Campesina 2013). To ensure this right, women and men of La Via Campesina recognize the need for comprehensive land or agrarian reform. Farmers need access to land as well as the guarantee of mechanisms for protecting and improving their methods of agriculture. Public policies and programs should augment peasant and indigenous cultures and ways of life.

In accomplishing these goals, the women of La Via Campesina reinforce the need to embrace and practice the tenets of food sovereignty. As the document proclaims:

Our struggle and action for Food Sovereignty has given us women the opportunity to make visible our historical participation in the development of the food systems in the world and the role we have

played since the invention of agriculture, in collection and propagation of the seeds, in the protection and preservation of biodiversity and genetic resources, placing us as primary emotional, ethical and social pillars. (La Via Campesina 2013)

It is only through the exercise of food sovereignty that true food justice can be achieved. The consequences of realizing these goals will not only create a more equitable global food system but will enhance biodiversity and environmental protection, as well as re-envision a more equitable family dynamic in which the role of women is finally recognized.

Phase 4

From 2004–2008, La Via Campesina reflected on its successes but also recognized that its rise to international power and recognition brought some unforeseen consequences. Taking center place on the world stage had the unintended effect of catapulting the organization into venues and situations that it might not have been completely prepared to operate within as a still-fledgling movement. As such, it decided to re-center and refocus its internal structure. Part of this included better training for member organizations as well as solidifying regional and local connections. The 2004 Fourth International Conference in Itaipu, Brazil, embraced the concept of *mística* or the "shared ceremonies or performances that build cross-cultural peasant solidarity" (Martínez-Torres and Rosset 2010: 164):

The attempt to (re)create, maintain and strengthen a peasant identity is a key cultural 'glue' that helps hold La Via Campesina together. There is a conscious sense of building a 'farmer pride' and the assertion that the "survival of peasant farmers is not something that just concerns rural areas, it is a matter that concerns all of society", there is a strong feeling that peasants are 'for humanity', yet have long been excluded from the cultural projects of most countries." (Martínez-Torres and Rosset 2010: 166)

It was during this period that La Via Campesina also embraced additional organizations in Asia and Africa. However, this too, presented problems, including how to negotiate cultural differences and language barriers.

Here the role of *mística* played a powerful function, as groups from around the world,

representing their cultural and religious heritages, would utilize the role of powerful imagery and symbolism to communicate a strong sense of solidarity. As Martínez-Torres and Rosset note, “[it] is remarkable in today’s world that a movement can be coordinated by a Muslim and incorporate Christians, Hindus, Buddhists and members of many other religions, together with radical Marxists and social democratic atheists” (Martínez-Torres and Rosset 2010: 166). By drawing together people from different global regions and from diverse cultural and religious backgrounds, La Vía Campesina continues to embody the potential of mass mobilization but also the challenges faced by transnational justice movements.

Conclusion: Challenges and the Future Ahead for La Vía Campesina and Food Sovereignty

Phase 5

Ultimately, the demand by organizations such as La Vía Campesina and its progeny, food sovereignty, is a certain call for the reflection upon, and eventual reconstitution of, the notion of the moral economy. When applied to the plight of the people of La Vía Campesina, “the issues of what values are commensurable, of what can be turned into a commodity, and of what natural or commonly held resources can be appropriated for private use and profit also loom large in the rural poor’s understanding of justice” (Edelman 2005: 332). Over a century ago, British scholars such as E. P. Thompson and James Scott already recognized the degree to which “‘markets’ are political constructions and outcomes of social struggle.” Moreover, the notion of the “market” during their theorizing was contested among economists and social theorists but basically referred to a specific location where specific goods were stored and traded. And, as Edelman remarks about the market “[o]nly later did it assume the metaphorical and deterritorialized qualities that increasingly adhere to it” today (Edelman 2005: 332). Ultimately, our current conception of the market has facilitated the

disassembling and dismembering of concrete social relations and locations.

In other words, the cultural value of food and agriculture increasingly falls victim to political, economic, and social ideologies that understand, and advocate for, food to be understood as any other common commodity. As a common, culturally dislocated commodity, food loses its historical heritage. It is under these conditions that La Vía Campesina continues to build and straighten its cause. “Thus, resistance is broadened beyond visible confrontations to include partially hidden forms, sites and strategies based on tradition, cultures, and alternative visions of how the world should be” (Desmarais 2007: 191). Perhaps the most important is the process of organization and protest itself. From its inception La Vía Campesina has faced obstacles, negotiated compromises, encountered and evolved in the face of changing global conditions, and, all the while, engaged in positive resistance to local, regional, and international forces of injustice. Despite containing a multitude of identities La Vía Campesina and food sovereignty continues to work toward inclusive relationships across cultures, practices, religions, and political ideologies.

In all of their efforts, the member organizations of La Vía Campesina has struggled to maintain a common identity while respecting difference, a “unity in diversity at the cultural level” (Martínez-Torres and Rosset 2010: 166). As members commonly remark, the movement makes them feel like a part of something bigger, a global effort to improve livelihoods, share their cultural traditions, and protect the environment, which is so essential to the land and production of food. As Desmarais notes, “peasants and farmers are using three traditional weapons of the weak – organization, co-operation, and community – to redefine ‘development’ and build an alternative model of agriculture based on the principles of social justice, ecological sustainability, and respect for peasant cultures and peasant economies” (Desmarais 2007: 200). As a transnational movement, La Vía Campesina and food sovereignty has globalized hope in the face of globalized injustice. Using food and agriculture as the bedrock for the movement, La Vía

Campesina represents a hopeful future for both nature and humanity.

Introduction

Large-scale land acquisitions (LSLAs) for the production of food, animal feed, and, especially, biofuel have become a controversial issue in global affairs, which are laden with massive

ethical challenges. LSLAs, commonly referred to as “land grabbing,” are a worldwide phenomena, the incidence of which has risen sharply since the 2008 global food crisis and has been estimated to have surpassed the acquisition of over 150 million hectares of land worldwide. The contemporary global rush by investors and states to acquire high-quality agricultural land is linked to ethical concerns, for example, when land deals lead to the forced displacement of local populations that previously had customarily worked and subsisted on such lands previously or when domestic food production is displaced by biofuel production for export for foreign markets. Given how recent LSLAs are, the scholarly literature on the ethics of LSLAs is at incipient stage. As such, this entry offers a preliminary discussion of the ethics of LSLAs informed by a global ethics perspective. The first section provides an overview of key definitions, characteristics, and trends of LSLAs. The second section explores the idea of a global ethics as it relates to the study of food and agriculture. The third section applies global ethics to the case of LSLAs by posing and discussing two questions: Is acquiring large quantities of land ethical? And when can LSLAs be considered ethical/unethical?

Large-Scale Land Acquisitions: Definitions, Characteristics, and Trends

LSLAs is only one of several terms scholars have used to describe the proliferation of land deals. Other commonly used terms in the literature and public discourse include cropland expansion, land grabs, land grabbing, and the global land rush, to name a few. For the purposes of the analysis here, LSLAs is used because this term has become the most widely used in contemporary policy discourse. However, it is important to acknowledge that this term is not a neutral one and some commentators have argued the term acquisition is a legitimating discourse to justify the practice of LSLAs. The word “acquire,” it has been argued, makes reference only to the actions of those acquiring land and evokes market-based transaction between willing buyers and sellers. This

particular semantic frame can render invisible the existence of, and consequences for, land users, who may not be the party selling land. By comparison, the term land grab evokes something very different. A grab, like a “power grab,” suggests an unfair appropriation of something and this is a cogent reminder of the normative power of discourse and framing.

Scholars and policymakers have developed several definitions of LSLAs to distinguish it from other forms of land purchases and/or appropriation of natural resources. Some definitions seek to establish criteria in order to distinguish land acquisitions from other forms of appropriation and to provide a basis for an empirical methodology, while others seek to identify and understand the asymmetrical power relationships implicit in land acquisitions. These are considered below.

Geographer Annelies Zoomers (2010) defines LSLAs as recent large-scale, cross-border land acquisitions that involve leases of over 30 years or direct purchases of a size greater than 5000 ha carried out by private firms or initiated by foreign governments. Although here definition can be applied beyond food and agriculture, this definition is useful because it brings into focus several important features such as acquisitions’ transnational/transborder quality, the modalities of acquiring of land, criteria for distinguishing “large” from “small”, and incorporates the key actors involved into analysis. A recent, influential global study of LSLAs (Anseeuw et al. 2012, p. 18) employed a similar definition based on the following features: transfer of rights to use, control, or own land through sale, lease, or concession; implies a conversion from land used by smallholders, or for important environmental functions, to large-scale commercial use; deals 200 ha or larger; and not concluded before the year 2000.

In a recent article, Borras et al. (2013) argue that there are severe limits to defining LSLAs according to size and type because doing so can obscure what is unique to contemporary land deals, most notably, their potential long-term implications for the global agri-food system as a whole and trajectories of agrarian change. Franco et al. (2013) build on more recent scholarship to suggest that definitions of LSLAs should

incorporate three key dynamics of social relations: the *assumption of control* over resources by one party over another and how benefits are accrued, the *modalities of acquisitions* and the *source(s) of capital*, and consideration of how the contemporary global political economy context that is *reconfiguring power relations across and between the north and global south* is altering the political dynamics to legitimate/challenge land deals (Franco et al. 2013).

Scholars and policymakers have found it difficult to obtain a precise picture of the scope and depth of LSLAs. The details of most land deals are not made public and there is a general lack of transparency about the nature of these contracts and the actors involved. Because of this lack of information, analysts have responded by developing multiple methodologies to assess the extent of land acquisitions based on the information available. Lorenzo Cotula (2012) summarizes the findings of recent studies noting the total quantity of land acquired is 51–67 million hectares and that this occurred in the period between 2001 and 2010. To put this in perspective, this land total is roughly the size of Ukraine. A much higher figure has been reported by the international nongovernmental organization, Oxfam; its most recent report on land acquisitions estimated that up to as much as 227 million hectares have been acquired globally (Oxfam 2011). The key point relevant for this analysis is that regardless of which figure is closest to the true amount, all these figures laude massive volumes of land being acquired.

Existing data confirms that the proliferation of LSLAs is a *recent* phenomenon. The vast majority of land deals had taken place since 2005 and reached record levels in 2008–2009 (Deininger et al. 2011), which was at the peak of the 2008 global food crisis. Because the proliferation of LSLAs spiked in 2008, most analysts consider the global food crisis a major driver of LSLAs.

LSLAs are also a *global* phenomenon. Whereas media attention has focused disproportionately on sub-Saharan Africa, where rural poverty is significant and which is a major site of land deals, LSLAs are occurring in all regions of the world, including Southeast Asia, Eastern Europe, the Americas, and Australia. The expert consensus is that land acquisitions are expected to

increase in the medium term due to high and rising prices of, and growing global demand for, agricultural goods. This suggests that LSLAs are becoming a “normal” feature of the global agri-food system.

There is also considerable heterogeneity that occurs across LSLAs. For the purpose of this article, two key dimensions of heterogeneity are particularly important. The first dimension is the intended production outcomes of LSLAs. In other words, LSLAs for what? The vast majority of land deals are for the production of biofuels and bioenergy (Anseeuw et al. 2012; Deininger et al. 2011). Key feedstocks for the biofuel production process include sugarcane, corn/maize, palm oil, and soybeans. This trend is consistent across all regions of the world although the selection of crops varies by region according to their suitability to local conditions. The increasing shift toward renewable fuels and “green energy” is a major driver of land acquisitions. For example, the European Union’s renewable fuels mandate requires that 10% of transport fuels be supplied by renewables by 2020 which is estimated to require substantial imports of biodiesel inputs, mainly from palm oil produced in South America and Southeast Asia (see Anseeuw et al. 2012, p. 26).

The second dimension of heterogeneity is the range of actors engaged in the acquiring land. On the acquiring side of the equation, research has shown that transnational corporations (TNCs), including those that specialize in food and agriculture, such as trading houses, supermarket chains, and renewable energy producers, are acquiring land to ensure the supply of agricultural inputs and expand vertical integration strategies right down to the control of the farm. Financial actors are increasingly prominent, ranging from investment banks, equity funds, and pension funds that engage in acquiring land directly or as partners in new agricultural ventures. The motives of financial actors vary, but in general they are influenced by widely held view that the global agricultural sector will be a major source of future profits as commodity prices continue to rise. Because of these trends land is now a highly desirable asset class. States are also engaged in acquiring land abroad. For example, China, South

Korea, and the Gulf states are directly and indirectly involved in LSLAs through the operations of state-owned enterprises and sovereign wealth funds. In addition, these states are providing other forms of inducement, including subsidies, special loans and financing, and tax breaks to domestic firms seeking to acquire land overseas. Similarly, subsidies, loans, and tax breaks to companies engaged in renewable energy in the North also act as a direct driver of land grabbing (Cotula 2012). Local elites and domestic firms are also engaged in acquiring land; however, this is occurring for deals at much smaller scales than international ones (Cotula 2012).

Global Ethics and Land Acquisitions

Global ethics (also known as world ethics or cosmopolitan ethics) is an ethical perspective that is useful to unpack the many ethical challenges posed by LSLAs. This is not to suggest that global ethics is the only, most appropriate or exhaustive ethical approach to the study of LSLAs. Rather because global ethics as an approach considers how globalizing processes and the deepening interconnections among individuals, states, and organizations across space and time can produce socially desirable or undesirable outcomes, and given that LSLA are global-scale phenomena makes global ethics a logical point of departure.

The basic argument for a global ethics is put forward by the philosopher Nigel Dower in the book, *World Ethics: The New Agenda*. Dower (1998, p. 2) defines global ethics as “an ethical theory or approach which puts forward a set of norms and values to guide our relations with the rest of the world.” A basic premise of global ethics is that an individual’s ethical obligations are not limited to their immediate/local community, be it their family or country. Instead, ethical obligations are posed as extending to the global scale. Thus, the intellectual goal of global ethics is to arrive at theoretical and practical positions of how to behave ethically given individuals are interconnected at the global level. For Dower and many other global ethicists, a few simple principles can be said to form the core of a global

ethical perspective: solidarity, pluralism, and peace. As such, global ethics are not a precise, strict ethical code but rather a different way of approaching rights and obligations at the global level that is not trapped by conventions such as the territorial authority of the state. Despite the skepticism that many have regarding the idea of global ethics, there are many examples of actually existing global ethics operating in the conduct of global affairs. Global ethics are visible in the creation and implementation of international human rights, international development assistance, and transnational social justice movements such as the fair trade movement (Dower 1998).

Global ethics can be applied to many areas of social life, including food and agriculture. However, it is important to distinguish global ethics, which are general in scope, from applied food and agricultural ethics, which are designed to guide the conduct of food and agriculture professionals. Today, global ethics are visible in several areas of food and agriculture. To illustrate this point, take, for example, fair trade coffee. Unlike a decade ago, fair trade coffee today has near ubiquitous status. Fair trade coffee is sold at high-end coffee shops in major metropolitan centers but also increasingly in far-flung places, such as gas stations in isolated, rural communities. The relevant point here is not whether people choose to consume fair trade coffee or not, or the extent to which such products are available, but rather that today fair trade coffee (similar to sweatshop labor-free consumer goods and organic foods) reflects greater global awareness of the global-scale social and ecological effects of our consumption choices. This awareness translates into significant changes in the practices of individuals and groups at the level of consumption and production.

Some Ethical Questions Raised by Land Acquisitions

A global ethics perspective is well suited to the study of LSLAs because so many land deals are transborder transactions consisting of relations between individuals and groups. These relations can result in positive or negative outcomes, broadly defined, in reference to the key principles

of global ethics: solidarity, pluralism, and peace. What does global ethics have to say about LSLAs? This ethical discussion is developed below through the consideration of two questions.

Is Acquiring Large Quantities of Land an Ethical Act?

Any discussion of land acquisitions today should be clear that these refer to very specific types of transactions involving significant quantities of land. Thus, it is important not to conflate LSLAs with other types of general, smaller-scale exchanges of land, which present their own unique set of ethical dilemmas (e.g., land inheritance within the family, illegal squatting, etc.).

A useful way to begin to situate the ethics of acquiring large quantities of land is to examine the recent past for a comparable situation. LSLAs were a central feature of colonialism and imperialism. The colonization of the Americas and much of the non-European world, by Spain, Portugal, Holland, France, and England, is an example that should be familiar to most readers. During that period, colonial and imperial powers justified land acquisitions, including the use of violence against indigenous peoples, by invoking their moral and religious beliefs. This included the belief that European peoples were superior to indigenous populations, even believing such peoples to be subhuman. This led to a general situation of massive physical and cultural violence against indigenous populations who were forcibly displaced, sometimes murdered en masse, from their traditional territories to secure territory and resources. The effects of colonialism and imperialism continue into the present. The legacies of cultural destruction and racism remain a salient policy issue in many former colonies such as Canada and Australia. Today's political geography is the direct result of past land acquisitions; most nation states in existence today were previously former colonial territories. Although certain colonial-like situations continue to exist in the modern world, it is no longer a defining feature of modern life.

Today's LSLAs bear some resemblance to colonial and imperialism in so much as it appears that vast tracts of land are being appropriated in

developing countries by powerful actors at the expense of poor, vulnerable groups. Since the practice of acquiring large quantities of land first began attracting media headlines in 2008, land deals have been labeled widely as neocolonialism and imperialism. LSLAs have set off a wave of global concerns about the negative impacts of land deals on poor farmers in the global South; this has resulted in significant transnational advocacy seeking to curb and/or to stop land deals from taking place. The direct comparability between LSLAs today and colonialism/imperialism practices of the past is an important intellectual question (Robertson and Pinstup-Andersen 2010; Alden Wily 2012).

There are major and important difference between land acquisitions today and past practices. First, land acquisitions today are taking place in the context of a globalized economy. Second, the vast majority of deals occur through market-based transactions such as purchases and leases, instead of appropriation by physical force or other forms of bilateral territorial treaties (i.e., such as the practice of territorial treaties among imperial nations and indigenous peoples that created the reserve system in North America). It can be said that current LSLAs signal the creation of a global land market. Such a development immediately raises difficult questions about whether land should be further subject to enclosure and commodification given that, historically, such processes have tended to increase inequality and privatize public resources, which may produce social conflict. Furthermore, many of the actors engaged in land acquisitions, such as agri-food corporations and institutional investors, are very powerful actors in today's economy, and because farmland in developing countries is relatively inexpensive and poorly governed in many cases, this leads to situation of asymmetries between buyers and sellers. Many have argued that these types of scenarios likely increase the inequality of land ownership within and across countries. The past has repeatedly shown that situations of highly unequal patterns of land ownership and access to resources lead to social and political conflict. From a global ethics standpoint, the proposition that acquiring large quantities of land may be

regarded as unethical in light of historical practices is to be expected.

When Are Large-Scale Land Acquisitions Ethical? When Are They Unethical?

This section considers the question of LSLAs slightly different than the preceding section by drawing on global ethics to establish some general guideposts to determine when acquisitions can be said to be ethical or unethical. Thus, what is offered below is an intellectual exercise of thinking through idealized types.

LSALs are most likely to be consistent with global ethics when communities who may be potentially affected by a land deal have some form of meaningful input into the decision-making process over land deals (this can be direct and indirect), there are net and significant economic and social benefits for the communities, and these deals operate in ways that support sustainable development. Importantly, land deals must support pluralism; that is, that it permits individuals and communities the option to continue living in a manner consistent with their preferred sociocultural norms and mores. In contrast, LSLAs are most likely to be unethical from a world ethics perspective when communities cannot participate in decisions that will affect them, when they lose control and access to the productive resources vital to their livelihoods, and when land deals result in social breakdown and ecological damage.

The term community is employed here instead of other units of social organization, such as the individual or the state, because this concept best contextualizes the on-the-ground realities of LSLAs. Most acquisitions occur in rural areas where agriculture is the primary, or at least a significant, source of livelihood for the community, and also because land plays an important social and cultural function for the community such as when cultural practices are deeply intertwined with working the land. Bringing the community into focus is all the more vital because most of the actors engaged in land acquisitions often think of only the land as commodity and not the social context/meaning of land.

The autonomy of communities and pluralism are linked concepts that are given considerable

weight in a global ethics perspective. Autonomy is used here to refer to the capacity of individuals and communities to make decisions over how they will live their lives. Autonomy means different things to different societies across space and time. For example, in Western society, there is a strong association of autonomy with individual liberty and democratic political systems. In other societies, autonomy may be defined vis-à-vis religious beliefs and traditional cultural practices. Global ethics takes autonomy seriously but recognizes that autonomy is fluid and always constrained by sociopolitical structures.

Pluralism is used here to refer to ethical position that accepts and respects that values, morals, and norms differ among communities/societies/nations. Pluralism requires that we acknowledge other, alien ways of living as equally valid as our own. Consider, for example, the case of a LSLA that prevents pastoralists from accessing traditional grazing lands. If this situation results in the outcome that pastoralists must abandon raising cattle and find alternative livelihoods, then this is a case that goes beyond a conflict over access to resources but the unmaking of one groups' way of being. The point here is not whether pastoralists might be better off economically if they pursue alternative forms of employment, this may be one possible outcome, but rather that these individuals are forced by the actions of others to seek alternative livelihoods that may not be the particular group in question preferred choice.

From a global ethics perspective, it could be argued that net economic and social benefits suggest something much more than the flow of capital into a country and the adequate "compensation" for the purchase or lease of land. Of course, in the best of possible worlds, communities would receive not just a fair price for land but also related employment, new infrastructure, and additional resources to provide vital social services (e.g., health, education, etc.) for the communities. A major benefit would be if LSLA acquisitions could enhance domestic food security, for example, by increasing the production, quality, and availability of basic foodstuffs. The data thus far has been a major cause for alarm for analysis because it suggests the opposite is occurring.

A recent World Bank report found very few deals were resulting in significant employment and services for local communities (Deininger et al. 2011). Instead, many LSLAs are imposing significant costs on communities by reducing the access to communal lands and to water supplies. There is also evidence to suggest that many communities are receiving less-than-fair compensation – that is, if they receive any compensation at all – as there are many cases reported of nonpayment or delayed payment (Anseeuw et al. 2012).

Sustainable development is implicit in, and coherent with, a global ethics perspective. Sustainable development is particularly salient to the discussion of LSLAs because these deals in many instances necessitate a shift toward energy-intensive, industrial agricultural practices in areas where previously farming may have been practiced on a smaller scale and with a lesser ecological footprint. The logic driving many LSLAs is that investors can easily set up capital-intensive, export-oriented new agricultural production with a sufficient land base to ensure economies of scale. A related concern is that most land acquisitions are occurring in states with limited environmental protection toward agriculture. This raises concerns that LSLAs will diminish soil, air, and water quality and produce negative effects on the health of local communities. There is evidence this is already occurring (Anseeuw et al. 2012). Land acquisitions are creating situations that are "externalizing" the environmental costs and risks of agricultural production in a new way; the risk and costs are not borne by the consuming country but by the local communities where land has been acquired, or acquired from. Thus, from a global ethics perspective, land acquisitions are unethical to the extent that they endanger the ecological and social health of one community in order to meet the consumption demands of the populace of a distant country.

LSLAs for biofuels present a double-layered ethical dilemma. Gamborg et al. (2012) elsewhere identify that the ethical challenges associated with biofuel are (1) changing land use from food to energy production and the competition these creates with food production and (2) leading to

deforestation and increasing greenhouse gas emissions. Initially, the ethical debates about biofuels centered around whether states should support the production of biofuels, such as the decision by the US government and European Union (EU) to require that automobile fuels be blended with a fixed percentage of biofuel and the implications of these policies for land use change, farm policy, and farmer income at the national level. LSLAs for biofuel are the result of policy decisions taken by distant governments to support alternative energy, and this is clearly a transnational dimension. Toft (2012) describes this situation as the “food versus fuel” debate and draws on cosmopolitan ethical theories to argue that land acquisitions for biofuels are dubious from a global justice perspective because the benefits are enjoyed by rich consumers (i.e., who own automobiles and purchase biofuel-blended gasoline) whereas the burdens of biofuel production are borne by poor farmers in the global South, who have likely lost access to land and means of livelihood. From a global ethics perspective, the argument for supporting biofuel production because of its purported capacity to reduce greenhouse gases is not justified if it comes at the expense of one (poor, vulnerable) community for the benefit of the (wealthy consuming) other.

Conclusion

LSLAs for food and biofuel are recent global phenomenon that poses multiple and significant ethical challenges. Whereas many of the specific food and agricultural issues themselves are not entirely new, such as those related to sustainable development, biofuels, and industrial production methods, what is new is the way in which land acquisitions now place these issues squarely as ones of transnational significance instead of only local or national ones. Therefore, global ethics provides an appropriate starting point to consider the ethics of land acquisitions. Global ethics are already informing the development of new, global regulatory instruments, such as the United Nations-sponsored *Voluntary Guidelines on the Responsible Governance of Tenure of Land,*

Fisheries and Forests in the Context of National Food Security and Group of 20-sponsored *Principles for Responsible Investment in Agriculture*, which seek to promote more socially and ecologically responsible practices by investors and governments involved in land deals. Going forward, a major challenge will be whether such new transnational instruments will have the sufficient moral and legal force to address and prevent the most negative effects of LSLAs.

Summary

The recent global proliferation of large-scale land acquisitions for food, and fuel is a new and significant issue in the study of food and agriculture ethics. This entry examines large-scale land acquisitions for food and fuel from a global ethics perspective. The first section provides an overview of key definitions, characteristics, and trends related to large-scale land acquisitions. The second section explores the idea of a global ethics and situates it within food and agriculture ethics. The third section poses and discusses two questions related to ethics of large-scale land acquisitions.

Land acquisitions in post-conflict countries: A double edged sword?

Introduction

For nearly a decade, the discussion of the benefits and disadvantages of large-scale land acquisitions (► [Land Acquisitions for Food and Fuel](#)) has become a hotly debated topic characterized by strong positions. Proponents, including neoliberal scholars, corporations, and numerous host governments, welcome this recent trend and tirelessly emphasize its advantages, i.e., infrastructure development, technological transfer, revenues, and the emergence of new (regional) markets. Notwithstanding, most land deals turn out to be land grabs (► [Land Grabbing](#)) that have been linked to human rights violations, an inadequate participation of, communication with, or compensation of affected communities, a lack of thorough environmental or social assessments, and/or are devoid of the free, prior, and informed consent of the affected land-users. This being said (and despite certain risks), profitable conditions in post-conflict countries – as diverse as South Sudan, the Philippines, Sierra Leone, Papua New Guinea, Mozambique, or Colombia – increasingly attract investors to acquire vast areas for food or biofuel (► [Biofuels: Ethical Aspects](#)) production, mining, and carbon (► [Carbon Farming](#)) offsetting purposes. At the surface level, this trend may seem promising in terms of economic restoration (Locher and Müller-Böker 2014, p. 249). Yet, large-scale land commodification may jeopardize reconciliation processes and long-term peace prospects in vulnerable post-conflict societies where access to and control over land often remains contested. In fact, evidence suggests that, in many cases, local communities face dispossession, lacking compensation, long-term environmental damage, and a loss of their livelihoods resulting in new structural dependencies and food insecurity (► [Food Sovereignty and Agribusiness](#); ► [Food Sovereignty and the Global South](#)) (Cotula 2013, pp. 125–129; Fairhead et al. 2012, pp. 243–245). Particularly, (new) displacement or involuntary resettlement challenges the fragile stability of post-conflict settings which often adds to already existing violence-induced displacement (Ince 2014) and socioeconomic struggles. Emerging resistance against land grabbing may further

undermine conflict transformation efforts and provoke new violence.

This entry provides an overview of the current literature addressing the potential and dynamics of large-scale land acquisitions in postwar settings and, consequently, implications for conflict transformation and transitional justice. The discussion centers around the role of land in post-conflict societies and touches the scholarly debate of the interplay between political (in)stability- and peacebuilding-driven neoliberal interventions, such as foreign direct investments in agriculture or mining.

Postwar Perspectives on the Spatio-cultural Meaning of Land

Scholars agree that post-conflict situations remain strained for years or even decades and can easily relapse into violence at any time. During this social, political, and economic transition phase, post-conflict countries are doubly fragile and vulnerable. While the root causes tend to persist, conflict-related legacies – that are often closely intertwined with territorial or land disputes – prevent the endogenous capacity of societies to approach these root causes. Evidence shows that in 27 out of 30 intrastate conflicts (1990–2009), land-related disputes or grievances constituted one of the major causes, and respective post-conflict situations were more likely to relapse into violence again (Unruh and Williams 2013b, 535; Elhawary and Pantuliano 2013, 115). Yet, despite its importance for conflict transformation processes – and in sharp contrast to the “resource curse” debate (Collier and Venables 2011) – the “question of land” has long been neglected. Only recently have academic scholars and the international community taken on a more coherent and strategic approach to peacebuilding and related land issues. Notably, Unruh’s and Williams’ (2013a, b) work on the role of land and Rustad et al. (2012) book on high-value natural resources in the context of conflict transformation are important contributions. Yet, little attention has been paid to the social and symbolic dimension of land or natural resources in the wake

of conflicts. For most (rural) populations including peasants, indigenes, and pastoralists, the meaning of land goes beyond its mere territorial or physical features. In this view, land “refers not only to soils, but also to landforms, water balance, climate, flora and fauna together with land improvements such as resource management, which includes mobility, traditional institutions, indigenous knowledge, technical know-how, labour and capital available to the community” (FAO, UNEP 1999: 7).

While post-conflict situations may differ in many respects, they share certain features, and challenges they face such as reconciliation, establishing security and a functioning state, refugee repatriation, economic recovery, or social well-being. Consequently, conflict transformation is a complex process which is also characterized by various contradictions and risks on its path toward durable peace. Building on Galtung’s concept of positive peace, Reyckler and Paffenholz (2001: 12) refer to sustainable peace as a “situation characterized by the absence of physical violence; the elimination of unacceptable political, economic and cultural forms of discrimination; a high level of internal and external legitimacy or support; self-sustainability; and a propensity to enhance the constructive transformation of conflicts.” Unruh’s and Williams’ (2013a, 1) findings demonstrate that addressing land issues effectively in postwar situations can lay “the foundation of durable peace.” More important, it can be regarded as a pivotal factor of post-conflict stabilization – depending on the size of the displaced population and the political sensitivity of land conflicts. Furthermore, the (re-) distribution of land for appeasement and reconciliation has proven successful since the agricultural sector is the most common reintegration choice for former combatants. UNEP’s and UNDP’S (2013) joint analysis on the natural resource and demobilization, disarmament, and reintegration (DDR) nexus with regard to conflict risks and long-term peace prospects comes to the same conclusion. And, yet, these programs hardly tap into their full potential due to the limited availability of undisputed arable land in postwar situations (Unruh and Williams 2013a, 2).

Conversely, land and resource management constitutes a major challenge for conflict transformation. While the settlement of land disputes is key for a peaceful long-term development, postwar land governance may also entail risks in terms of redistributive justice and inclusiveness. In the aftermath of war, access to and control of land often remains a sensitive issue which may precipitate tensions and lead to a renewed destabilization of volatile post-conflict situations, as Unruh and Williams (2013a, 1) point out. In addition, during conflict, in many cases, new partly competing land claims and regulations may emerge, or title documents get lost, while previous (institutional) resolution mechanisms have often only negligible effects (Huggins 2009). Those who seek to pursue land include refugees or displaced persons who intend to, cannot, or wish not to return to their area of origin, opportunists that try to benefit from land redistribution schemes, ex-combatants, state actors, corporations, or others with claims dating back to previous regimes (Unruh and Williams 2013a, 63). Analyzing interlinkages between access to land, business (► [Access to Land and the Right to Food](#)) and successful conflict transformation, Elhawary and Pantuliano (2013, 117) argue that in some cases refugees compete for land even directly with “the state and its foreign or local business partners.” They suggest that violent conflict not only disrupts political, social, and economic structures but also catalyzes social changes and rapidly alters tenure systems and/or regulation mechanisms. Unruh and Williams (2013a, 7) further observe that displacement, experienced violence, and the breakdown of tenure-related institutions and norms change “land use, settlement patterns, and production.” Accordingly, post-conflict land governance needs to consider land and property issues that emerged before, during, and after the immediate conflict and pay particular attention to questions of secondary occupation and elite capture.

Neoliberal Peacebuilding and the Promises of Land Acquisitions

Neoliberalism’s closely intertwined relationship with post-conflict development has become well

recognized in much of the peacebuilding literature. Neoliberal peacebuilding comprises a set of economic and political measures that primarily promote democratization, early elections, and – most important in this respect – a free market economy (see Campbell et al. 2011). While much has been written about the neoliberal nature of current peacebuilding interventions (Woodward 2013, pp. 141–143, Newman et al. 2009), the literature on post-conflict land investments is largely limited to corporate social responsibility (► [Corporate Social Responsibility and Food](#)) readings (Tripathi 2008). Once a country is labeled “post-conflict,” international organizations and financial institutions (► [Agriculture and Finance](#)) are able to launch (neoliberal) peacebuilding programs and to open new markets for investors. However, researchers and practitioners have not given due weight to the social dimension of postwar development which again questions the durable objective of peacebuilding. Corporations and liberal politicians emphasize and promote the stabilizing and long-term benefits of what they refer to as “corporate peace” (Haski-Leventhal and Schippa 2013) which, in turn, legitimizes and pushes foreign direct investments forward. Despite unreliable legal systems, untransparent regulations, corruption, and unsecure property rights, anecdotal evidence suggests that corporations are increasingly encouraged to take chances if returns are worthwhile. Economics scholars emphasize that investors may largely contribute to economic recovery, infrastructural improvements, and technology transfer: developmental factors which matter even more in post-conflict situations (Sweetman 2009). Corporations may, however, also draw large profits from insecure postwar contexts by playing elites off against each other or urge authorities into large-scale land acquisitions with the promise of inward benefits (Pugh 2014, 4–5). Criticizing the remodeling of war-torn political economies along business lines, Pugh outlines how post-conflict countries are literally coerced to open up and provide an investor-friendly environment to compensate for security risks. Along with other pull factors, such as substantial donor inflows supporting reconstruction or

early-to-market advantages, the neoliberal postwar orientation underpins foreign direct investments in land and resources. Not only investors, but also post-conflict governments may benefit from commercial land acquisitions, mainly in terms of state revenues, infrastructure development, or rural income-generating opportunities. In order to justify large-scale land commodification, postwar governments usually either refer to the national yield gap or declare vast areas as “idle and marginal” or even “wastelands.” Alternatively, ruling elites may take advantage of land concessions that allows them to increase their control over certain areas and thus, to consolidate their power. Yet, despite its promising benefits, the acquisition or commodification of land faces various post-conflict challenges, i.e., the coexistence of multiple land tenure systems or legal ambiguity, ranging from conflicting claims to unclear boundaries or access rights (Unruh and Williams 2013b, 537–538). With that said, interlinkages between land investment implications, post-conflict societies, and reconciliation will be outlined in the following section.

The Interplay of Land Acquisitions, Conflict Transformation, and Reconciliation

It is widely understood that postwar development is not only confronted with continuing “unpeaceful relations” but also with land-related conflict legacies, such as farmland and forest degradation, heavily exploited natural resources, and destroyed infrastructure (Unruh and Williams 2013b, 536). Yet, few scholars have explored the impact of large-scale land acquisitions on vulnerable postwar countries or its potential and risks to conflict transformation. As outlined above, the benefits of large-scale land acquisitions have been widely discussed. Most studies, however, conclude that even under favorable conditions, the impact on affected communities and the environment remains ambivalent and tends to be rather harmful, ranging from violated land rights, inadequate consultation, lacking compensation, to challenges for (local) food security (Locher and

Müller-Böker 2014). Here, Millar’s (2015) research on post-conflict Sierra Leone offers a starting point. By addressing the research gap of microeconomic peace dynamics, he demonstrates potentially destabilizing effects of land grabbing, i.e., increasing economic inequality. Nevertheless, Millar does not consider communal coping strategies or potential synergies between war experiences and means of resistance. Drawing on assemblage and current social movement writings, Hennings (2016) offers further insights into the consequences of resistance against land commodification for socioeconomic and political conflict transformation dynamics by referring to the case of Bougainville.

Critical readings emphasize the issue of power disparities that may result and manifest in the context of large-scale land acquisitions. Through land concessions the state expands its control over respective territories and its inhabitants, what Vandergeest and Peluso critically refer to as “property rights over people” (1995, p. 394). They argue that the state enclosure of natural resources, i.e., the acquisition and (re-) distribution of land, goes beyond the mere material appropriation of land and commodities. It is much more an act of gaining control over social, cultural, and economic resources which is sometimes closely associated with elite capture (Hall 2013). In post-war contexts landmine clearance poses a particular problem, as Unruh and Williams (2013a, 13) point out by using the case of Angola where these dynamics fueled land grabbing and corruption. Generally speaking, the top-down exclusive commodification of land, forests, and minerals can easily destabilize vulnerable post-conflict situations. Thereby, land is not only contested but its transformation into valorized capital is contingent upon the separation of land from social-cultural meanings (Green 2015; Gertel et al. 2014). This changes the relation between the land and its former owners or utilizers inevitably and replaces it with a primarily economically motivated relationship that often holds resemblances to exploitative patterns (► [Soil and Agriculture](#)). Taking the impact of commercially motivated land use changes on post-conflict identities into account, Gertel et al. (2014) contribute a

profound analysis of multilayered conflict dynamics resulting from land and resource investments in Sudan. Moreover, women (► [Women in Agriculture](#)) in post-conflict situations are particularly affected by land acquisitions, eviction, and at the same time are often excluded in terms of compensation payments that – if paid at all – are usually handed over to the male head of the household. Moreover, post-conflict societies have not only experienced violence but have also undergone social (gender) configurations which continuously influence contemporary socioeconomic, political, and cultural developments.

Confronted with eviction and dispossession, communities need to find coping strategies which often adds pressure to urban centers where, in the aftermath of war, people struggle even more with high unemployment rates, inadequate housing, and poor infrastructure. In instances of extreme oppression or coercion – in some cases, (in)directly supported by investors or donors, i.e., through controversial infrastructure or land governance projects (Fairhead et al. 2012; Neef et al. 2013) – communities may be pushed to engage in more confrontational and riskier forms of resistance. In this regard, the promises of large-scale land acquisitions may lead to government-led civil society constraints, i.e., the marginalization of trade unions (Pugh 2014, 5). Furthermore, human rights violations can undermine the transition towards peace since renewed and transformed grievances may contribute to an increasing popularity of (former) rebel groups (Hennings 2016). Accordingly, violence may easily escalate and undermine state authority. This may involve destructive long-term impacts particularly in vulnerable post-conflict societies, disrupt peace and reconciliation processes, or even promote new armed conflicts (see Hataya et al. 2014 on Colombia, Shanmugaratnam 2014 on South Sudan). Unruh and Williams (2013b, 540) describe the risks associated with large-scale land deals and exclusive consultations (e.g., with regard to former combatants or returnees) that may give rise to social unrest. They emphasize that from economic restoration up to reconciliation and reintegration, everything depends on a reliable land management system. Filling the

institutional void and reforming land tenure may, however, take time to conform to existing customary rules and, eventually, to be able to contribute to conflict transformation.

Conclusion

Notwithstanding that the land commodification, peacebuilding, and reconciliation nexus is underexplored, it becomes evident that land and natural resources are not only a sensitive issue but remain contested in the aftermath of war. While most of the peacebuilding literature considers economic recovery and foreign direct investments pivotal to sustainable peace, land constitutes a key instrument for appeasement and reconciliation. In fact, large-scale land acquisitions may contribute to conflict transformation and peacebuilding if they are transparent, highly inclusive, and consensus based. Empirical evidence, however, illustrates the difficulties of such social responsibility-driven undertakings in countries without conflict-related legacies. Embedded into the global land rush debate, the entry also detailed the debates surrounding elite capture and corporate benefits of instable post-conflict situations. It outlined obstacles associated with inclusive adequate consultation of affected populations, including ex-combatants, refugees, as well as returnees, and the multiple challenges postwar land governance faces, such as legal pluralism or ambiguity. The discussion underlined how exclusive land deals, eviction, and coercion may lead to resistance, social unrest, or even (renewed) violent conflict. In summary, large-scale land acquisitions in post-war countries as implemented today may pose a serious risk to political stability and conflict transformation, despite some promising surface-level benefits.

Introduction

The application of force to coerce individuals to illegally give up their land or the otherwise illegal dispossession of land, a process known as “land grabbing,” is a violation of human rights – the arbitrary deprivation of property outlined in the *Universal Declaration of Human Rights* (Article 17). Land grabbing is the most legally and ethically problematic form of large-scale land acquisitions. However, if direct or indirect force is not applied in the process of large-scale land acquisitions nor any laws broken and the individuals involved receive sufficient benefit in exchange

for their land, are the exchanges necessarily ethical? Based upon a human rights-based perspective, this entry argues that human rights cannot be analyzed in isolation, but must be evaluated in totality in order to contextualize the vulnerability and duress experienced by those transferring their land. In doing so, it expands our conceptualization of what is considered “land grabbing” and what is not. Over the last decade, the majority of large-scale land acquisitions have taken place in countries where human rights are violated. In order for large-scale land acquisitions to be ethical, human rights must be met and protected to ensure that choices are truly free and fair. This is not a practical argument, made to improve the process, but an ethical argument based upon protecting the lives and livelihoods of smallholder farmers and pastoralists, ensuring their choices are truly free and fair, not simply the product of a lack of options made from a position of vulnerability.

Land Grabbing and Basic Human Rights

The definitions, characteristics, and trends of large-scale land acquisitions are detailed elsewhere in the volume (see “► [Land Acquisitions for Food and Fuel](#)”). “Land grabbing” is the sale or lease of land that is used on a permanent, seasonal, or cyclical basis by individuals who have not agreed to the transfer of that land, whose land is taken by illegal means, with or without force. International organizations, governments, and researchers focus upon large, foreign land acquisitions exceeding 5,000 hectares in size. The utility of this qualification is challenged below. Land grabbing occurs in diverse contexts, resulting in a range of negative outcomes. Consequences typically include displacement, loss of income and livelihood, deepening of vulnerability, food insecurity and undernourishment, biodiversity loss, and environmental damage to air, land, and water (e.g., Makki and Geisler 2011; Shete and Rutten 2015). National priorities, such as attracting foreign direct investment or entrenching political control, can encourage or facilitate land grabbing at the expense of small-scale

farmers and pastoralists, whose land is transferred to investors (Lavers 2012; Rahmato 2014).

Land grabbing is a subset of the much larger process of large-scale land acquisitions. The phenomenon is not new, but has occurred at an unprecedented scale during the past decade. Large-scale land acquisitions are often justified as a means to increase agricultural productivity and efficiency or that such transfers take place in areas where land is un-/underused. Advocates of land acquisitions point to examples of good agricultural investment practice that benefit all parties as evidence that large-scale land acquisitions are ethical. However, the positive examples tend to be atypical arrangements, such as public-private-community partnerships (e.g., Djire et al. 2012). In most instances, the impact on individuals and communities transferring their land to investors has been negative. Investors may grow nonfood crops or export their yields, decreasing the amount of food commodities available in local markets. Investors may overuse and pollute water resources, decreasing food production and quality within the vicinity (Via 2011). A World Bank study of large-scale land acquisitions demonstrated that investments did not create a significant amount of employment, which would act as a replacement for lost livelihoods (Deininger et al. 2011). Households that previously relied upon their own land for food consumption become reliant upon scarce and inconsistent employment income and are affected by volatile food prices, thus increasing their vulnerability to food insecurity (Hossain and Green 2011). A “surplus” of labor, due to mechanization or crop choice, creates high levels of unemployment and can force wages down (Li 2014). The negative outcomes are particularly pronounced in countries where the rule of law is weak, where governments have a limited ability to monitor activities and enforce contracts, and wherein human rights are regularly violated.

Margulis (see “► [Land Acquisitions for Food and Fuel](#)”) defines large-scale land acquisitions as unethical when they are contrary to the principles of sustainable development and when an unfair burden is placed upon the poor to produce for the wealthy. While this is laudable progress in

assessing unethical practices in large-scale land acquisitions, this entry argues the most suitable place to understand the ethics of large-scale land acquisitions is with the individuals and communities affected and by analyzing the conditions within which their choices are made.

In the case of land grabbing, a legal rights violation takes place, that of the right to property and the protection against unlawful dispossession of that property. Within the context of large-scale land acquisitions, the illegal dispossession of land represents a minority – however many land acquisitions take place in areas of contested land ownership or wherein individuals and communities have not been granted appropriate property rights. Margulis (see “► [Land Acquisitions for Food and Fuel](#)”) argues that when those affected by land acquisitions have “some form of meaningful input” and when there are “significant economic and social benefits for communities,” large-scale land acquisitions can be ethical. However, the meaningfulness of such input is lacking if the focus is only upon coercive power. When human rights are not protected, meaningful input is spoken from a position of vulnerability and duress wherein few viable alternatives exist. It is, therefore, unethical to take the land and livelihood from individuals, families, and communities when they are experiencing a deprivation of human rights. Autonomy in decision-making is insufficient when those decisions are made from a position of vulnerability. This is an important consideration because a significant amount of large-scale land acquisitions that have taken place in the last decade have occurred in countries where human rights are not being met (Human Rights Watch 2016; Land Matrix 2015), thus calling into question the ethical nature of large-scale land acquisitions taking place in such contexts.

Suppose that a community of 250 households is coerced by the army to vacate their land, uncompensated, to make way for investors. This is unethical because their right to property is violated. Now, suppose the 250 households left on their own volition, but under the veiled threat of force by the army. This choice is not considered one made freely and fairly due to duress, and therefore the acquisition of that land is unethical.

Next, consider a single household within that community that lacks the ability to pay for desperately needed healthcare for an ailing child. The household is offered a fraction of the value of the land and due to vulnerability and duress accepts the offer as a means to access the needed care. Just as the threat of violence was considered as unethical due to duress, this exchange should similarly be considered unethical, as not being free and fair due to vulnerability and duress. Finally, suppose the community of 250 households has no access to clean water, education, healthcare, roads, markets, and other basic services, wherein chronic extreme poverty is the norm. The army offers access to these desperately needed services in exchange for their land, which will be provided by the national government in the area wherein they are being relocated. The community members accept and leave, and investors take over their land. Just as the single household had decided under duress and from a position of vulnerability, this communal decision should also be considered as having been made under duress, a result of chronic poverty, a lack of opportunities, and a result of having no access to basic services. Thus, in order for land acquisitions to be considered ethical, based on free and fair decision-making, all individuals involved should have their human rights met and protected. This would alleviate the duress and position of vulnerability, resulting in willingness due to choice rather than willingness due to a lack of viable alternatives.

Philosophers who have contributed to our understanding of human rights and social justice, including Kant and Rawls, considered decisions made under duress as not being free and fair. Individuals and communities experiencing chronic poverty, food insecurity, and ill-health encounter daunting choices with limited opportunities. For example, approximately 800 million people are chronically undernourished and are not free from hunger (see “► [Human Rights and Food](#)”). Such individuals do not experience security of person, nor have they attained an adequate standard of health and well-being (Articles 3 and 25 in the *Universal Declaration of Human Rights*). While cognizant of the challenges,

individuals who experience difficulties such as extreme poverty and chronic food insecurity are often left to choose between unfavorable options. For some, the consequence of their vulnerability results in the sale or lease of their land. That choice, however, should not be considered as having been made freely and fairly due to the duress and vulnerability caused by poverty, hunger, and ill-health. In order to have a willing-buyer and willing-seller agreement, the seller must not be forced, either directly by coercion or indirectly by extreme poverty. An ethical land acquisition, therefore, can only occur when those involved have their human rights met and protected. The minimum standard of human rights required would include the right to food, housing, education, healthcare, and security of person. The present objective is to outline the ethical case against large-scale land acquisitions made in contexts where these basic human rights are violated, not to list required rights, nor how those rights ought to be met and by whom.

This entry is not about how to facilitate business or to identify avenues to improve the practice of large-scale land acquisitions. Nor is this an entry about how local, national, and international food needs should best be met. This entry is about the ethics of large-scale land acquisitions, which commonly occur in contexts where human rights are violated. The ability to provide meaningful input is negated when human rights are lacking. Choice is neither free nor fair when individuals and communities have to decide between food, healthcare, and education and their land and livelihood. Requiring that basic human rights be met and protected for a land transfer to be ethical is politically problematic and appears to be impractical. However, it is not always necessary to be practical and pragmatic; change occasionally requires envisioning a future world that is inspirational and visionary. As it relates to food and agricultural ethics, when Peter Singer began writing about animal rights in the 1970s (e.g., Singer 1975), many felt the ethical argument was not practical or politically viable; however the way animal rights are thought about has dramatically transformed since that time. In many parts of the world, poverty is pervasive. Requiring that human

rights be met for large-scale land acquisitions to be ethical may prohibit business due to the neglect or the inability of governments. However, setting aside the need of foreign direct investment and the desire for increasing the flow of trade and instead focus upon the ethics of large-scale land acquisitions with regard to human rights, it is possible to envision a future wherein the absence of human rights amid such transactions would be considered abhorrent. This is an ethical case that inspires thought toward a future wherein all people, in all places, have their human rights met and protected.

Beyond Large-Scale Land Acquisitions

The academic and activist land grabbing discourses focus upon large, foreign agricultural investments. However, individuals and communities are negatively impacted by more than large foreign investors and the ethical consideration of land grabbing ought to be inclusive of those broader experiences. Activists and scholars have pointed out that significant amounts of land being transferred go to national investors, as opposed to foreign ones. While these acquisitions tend to be smaller, they occur in a much greater number. For example, between 2004 and 2009, nationals were transferred 97 % of land acquisitions in Nigeria, 78 % of land acquisitions in Sudan, 53 % of land acquisitions in Mozambique, and 49 % of land acquisitions in Ethiopia (Deininger et al. 2011). A similar process, a violation of human rights, enables these land acquisitions to take place. The poorest members of society are the most vulnerable to shocks, such as crop disease and commodity price fluctuations, as well as to challenges arising from outside of the agricultural realm, such as ill-health. A widow may sell her land because she lacks the resources to take care of her family, and a grandparent may sell her land due to healthcare debt. Li (2014) has pointed out that the loss of land and livelihood in these forms takes place within legal, long-term capitalist relationships. These sales, although technically legal, are not free or fair. The choices are made because no viable alternatives exist. Thus, when human rights have not been met or protected and due to

the lack of options and opportunities, the poorest members of society can become landless, without a livelihood and disenfranchised due to micro-land grabbing. The processes, size, and rate at which these transfers take place differ, but the cause of duress and vulnerability is the same: human rights are being violated and “willingness” is a product of a lack of options. It is noteworthy to add that these land acquisitions are not a result of poor inheritance laws, but of “willing-buyer, willing-seller” exchanges wherein the seller may only be “willing” because of duress and vulnerability caused by poverty, willingness when no other choices are available.

Conclusion

The process of illegally disenfranchising and displacing people from their land and livelihood, defined here as land grabbing, violates the right to property and the protection from unlawful dispossession of that property. The rights to property and protection from disenfranchisement, however, must not be considered in isolation from other human rights, such as security of person and an adequate standard of health and well-being. Concepts of consent, meaningful input, autonomy, and participation ought to be considered as being made under duress and from a position of vulnerability due to the deprivation of these human rights. Even if an individual has the right to property, a violation of other human rights, and the resulting vulnerability of those violations, creates an illusion of choice, willingness because no alternatives exist. An ethical large-scale land acquisition, therefore, can only be conducted when all parties involved have their human rights met and protected, enabling them to make free and fair choices.

Summary

This entry has argued that choices are only free and fair and decision-making only meaningful, when human rights are met and protected. The majority of large-scale land acquisitions that have taken place in the last decade have occurred

in countries where human rights are not being met (Human Rights Watch 2016; Land Matrix 2015), thus calling into question the ethical nature of large-scale land acquisitions taking place in such contexts. This entry also challenged the focus on large, foreign acquisitions, because the scale of smaller, domestic acquisitions can be just as large in totality and equality as problematic.

Introduction

Nowadays, decisions concerning production, distribution, and consumption of food are not only reviewed from perspectives like *food safety* but in relation to fairness in its distribution, the sustainability of food systems as a whole, or their impact upon cultural diversity or personal identity. The ones to address of all these decisions are those that have involved the establishment of regulatory frameworks with regard to food and agriculture research.

Agro-food sciences and the technological applications in this sector have the potential to assist all human beings to satisfy their *daily need for food* and not only in terms of survival *stricto sensu*. In terms of scientific-technological development, humans have never been closer to being able to provide each and every inhabitant of the planet with food suited to their specific nutritional needs. These ideas have repeatedly been highlighted in documents issued in the second half of the 1990s by institutions such as the OECD, the FAO, or the institutions of the EU which referred to advances in the field. Thus, for example, in 1998, the 5th European Union Framework Programme of Research and Technological Development underlined the potential of modern biotechnology vis-à-vis the obtaining of safe, *healthy, balanced, and varied* food. However, as it is known, this potential of food and agriculture research does not serve to explain the nature of the sociopolitical and economic tensions surrounding these advances, in particular those in agrobiotechnology. The law regulating this field has been created to mitigate potential conflicts of interests and untoward ethical practices reflected in this scenario of tension.

The laws, regulatory developments, and mechanisms of supervision currently applied to food and agriculture research are part of a fragmented model of global governance, divided into regulatory levels which compete among themselves. All of this gives rise to several questions: who created the different regulatory frameworks for food and agriculture research? What are the concerns they have addressed and where are they leading human societies? To answer these questions from a global and multicultural perspective is not easy. Law is an expression of culture which is intimately related to the geography, history, political sensitivities, and sovereignty of the states which created it. Nevertheless, on a global scale, there are a number of elements which can be critically analyzed. Among them, it is possible to study how foods have been predominantly considered as tradable commodities throughout history.

The Ethics Behind Food and Agriculture Law: Historical Background and Some Warnings Regarding Its Critical Analysis

The law is an instrument, even since the earliest societies, has been employed to resolve social problems. Compared with other mechanisms created with a similar purpose, the law is notable for its high degree of formalization and its coercive character. Nonetheless, there are significant limitations to its potential to resolve conflict. Why? Because in spite of its apparent strength, the task of the law is basically to impose behavioral guidelines (actions or omissions) upon a series of subjects, who are understood to be an important part of the problem. As the philosophy of law explains, the members of societies tend to obey the law either because they agree with the rules or for fear of sanctions, but the mere creation of a legal norm does not guarantee per se that it is going to be obeyed. However, there may well be an incorrect approach to the problem on creation of the law or the selection of behavioral guidelines that contribute nothing towards its resolution.

Contemporary food law systems are very complex systems relating to a multitude of aspects of production, distribution, and consumption of food. Moreover, their creation involves the participation of different entities, which range from local to international and are not immune to the influence of certain private stakeholders. But it is important to underline the fact that, to a certain extent, the complicated regulatory and oversight mechanisms employed share a common root with the food law that was already operational in ancient Rome. In which sense?

Food and Agricultural Law in Ancient Times

The societies of ancient Rome, Greece, or Egypt already had their own legal norms, and it is known that some of these referred to certain specific aspects of the food fact. This was an incipient *food law*, much simpler than today's in its objectives and means, but which in short prohibited or enforced certain behavior and advocated legal consequences for those who infringed its terms. With regard to the matter at hand, it also contained

a provision maintained by current regulatory systems. That is the consideration of food as a tradable commodity.

It has been said that the first few thousands of years of the history of humanity boiled down to the essential chances of survival. Though not exclusively, survival depended, and still depends upon, the response provided to the daily need for food (Teuberg 1989), and this explains why like other living creatures, humans developed different skills and techniques to obtain more and better food and drink. With the first tools, *Homo habilis* embarked on a journey towards what thousands of years later, and thanks to other milestones such as the mastery of fire, would be the food industry. As it is known, the most significant transformation would come with livestock and agriculture, barely 10,000 years ago. The production of food from plant species and domesticated animals is one of the characteristics of the new age: the Neolithic age. Archeological samples also provide evidence that in this era people already possessed technologies which – in the strictest sense – might be described as *food technologies*, in other words, knowledge and practical applications of principles of the science of the preservation, processing, preparation, packaging, storage or transport of food (Curtis 2001). Products of the land, already improved by agricultural or livestock farming, were transformed into more easily consumed and better tasting products. As long as 8000 years ago, harvests were already being stored in holes dug in the ground and then covered with clay (*Al-Fayyum*, Egypt).

Within the scenario of the first civilizations (Ancient Egypt or particularly the city-states of Greece and Rome) appeared the first juridical rules applied to food. Urbanization in ancient times increased consuming populations incapable of directly producing their own food, and there appeared agents specialized in food production and retailing. Knowledge with regard to processing, storage, or transport of food and drink would be crucial in the appearance of different *stages* between growers and end consumers (Burnett and Oddy 1994). This would be a

potential source of conflict, solution to which would be sought via legislation.

The first public controls of which there is evidence referred not so much to the processes of elaboration, as to the guarantee of contractual *bona fides*. This involved the supervision of prices, of systems of measurement (scales, tape measures) and quality control. In the ensuing centuries, the local administrative or judicial authorities of different countries would apply similar measures, designed to prevent charging exorbitant prices, giving short weight and the adulteration of food products (e.g., the English *Assize of Bread and Ale dating*, 1285). There was never any doubt – as mentioned already – that food was a consumer good.

The Food Law of the Diet Revolution (s. XVIII–XIX)

The eighteenth century saw a consolidation of the bases of what has been called the *diet revolution*, the progress of which accelerated in the nineteenth century. The confluence of industrialization and the processes of urbanization led to a significant increase in food production and in the population groups in a position to accede to this food. Western countries advanced towards an abundance of food which, in time, would be indicated as one of the features of welfare societies.

A key element in this process was scientific-technological evolution. In the preindustrial era, access to food was very limited and existed in conditions of poor hygiene. The modern model of production and distribution would seek formulae for efficient mass production of food with the aid of scientific advances and the development of technologies in agriculture, livestock farming, and food processing. The physiocrats in France, the Royal Economic Societies in Spain, and the English Agricultural Council are some of the institutions in whose documentations are recorded inventions and discoveries that improved food (Fernandez 2009). Creators of new strains and varieties, designers of sewing machines or pumps, proposals for methods of rotation, all of these would contribute towards agriculture and livestock farming gradually acquiring an industrial profile. Relevant too were the advances

regarding efficiency in mass production of food, overcoming the poor hygienic conditions of previous eras.

The *food policies* were aimed fundamentally at guaranteeing adequate food production and distribution in accordance with the health and safety parameters of the time. This was an age of confidence in market self-regulation and reinforcement of the idea of the *tradable* nature of food.

There would be no impact on regulations as a result of those critical reflections upon some aspects of food production and distribution that appeared in this era. One of the criticisms of this movement was the tendency “to put cooking into scientific, rationalized, technical and differentiated categories,” coupled with proposals for a return to “natural cooking” (Teuteberg 1989). Similarly, the Lebensreformbewegung movement at the end of the nineteenth century accused modern agriculture of ruining “pure food” and endangering people’s health in the quest for profit.

The Nutritional Transition of the 1960s

The demographic crises traditionally caused by famine decreased significantly from the mid-nineteenth century onwards, although many of the problems associated with hunger and malnutrition persisted until the second half of the twentieth century (Barona 2012). Political tension, economic crises, protectionist trade barriers, or wars (national, regional, or international) continued to have a major impact upon food supply.

In the first half of the twentieth century, the demands of an emerging civil society led states to reorder some aspects of food systems to avoid famine. There also appeared what is known today as the *human approach* to the food issue, that is, a journey begun at the start of the century with the institution that preceded the FAO, and which would lead to the proclamation of the human right to food within the Universal Declaration of Human Rights of 1948 (art. 25). The legal articulation of this human right, in spite of such important documents as the Declaration of Rome of 1996 or the *Millennium Goals*, has failed to go far enough. It is not clear where or how every person may claim their right to a food appropriate to their needs. Neither has the

question been addressed, certainly, of how societies should act when the need to satisfy that right proves to be incompatible with the legal status of tradable as applicable to food today.

In the second half of the twentieth century, the nutritional transition in Western societies began to become apparent. As a consequence of the industrialization of agriculture and improvements in preservation and delivery systems, the availability of food improved significantly in certain areas of the world. However, two major concerns persist. One is food safety. There is an absence of rules and control mechanisms that assure food quality in light of new production practices and the increasing distances food travels. A second concern is what Levenstein would describe as *Paradox of Plenty*. The so-called Green Revolution (which was more an agrochemical revolution) was based on massive fertilization campaigns and intensive pest control programs. The marked improvement in certain crops appeared to be the solution to an old problem (that of food shortage), but it created other new ones, such as the displacement of traditional crop varieties and undesired effects upon human and animal health, and on the environment.

In response to these concerns there the last decades has developed a food law that is new in terms of its contents. Food law will be new as well with regard to the subjects who create it or participate in its creation and in the territorial scales – from local to international – where it will be applied.

Contemporary Laws and Regulatory Mechanisms on Food and Agriculture Research: Their Main Characteristics

As studies show, human intervention in food production and preparation has not yet totally transcended the organic-biological character of food, although many changes have occurred. Historically, this character has conditioned food consumption and its commercial possibilities, which have depended on geographic and climatic location and on the existence of adequate systems for its conservation and transport. The contemporary

chain connecting those who cultivate raw materials to consumers is now virtually free of limitations imposed by time, climate or distance. Furthermore, commercial networks on a planetary scale coexist with traditional food systems or those of new creation in which producers are very close to the consumer, or consumers themselves participate in the consumption of what they consume.

How has *food law* evolved? It is important to remember that regulatory mechanisms are imposed by those who *de ius* or *de facto* hold political power. Contemporary globalization has blurred states, which have ceded significant areas of power to supranational entities. The loss of the state as a reference has meant that *food law* has ceased to be a coherent whole, created in a constitutional legal framework that adopts as a reference a series of values and principles. This era is characterized by a legal phenomenon that has been described as *multilevel fragmentation*, and on each territorial level, the framework and the values upon which law is based are different.

A very powerful image when explaining food governance is the existence of different levels of governance, dominated by different actors and with different views and who compete among themselves for hegemony over the food system. Regulatory regimes are no longer purely “tools to resolve conflicts”; they are now an instrument which helps those who on one scale or another hold power in the market to maintain their status quo.

Explaining Contemporary Governance and Food Law as Competition Between Regulatory Regimes

Conventional, state-based regulation is no longer equipped to supervise those food supply chains that transcend its borders. Given the particularity of food as consumer good and its deep-rootedness in the traditions and cultures of countries, until a couple of decades ago, state laws had represented an obstacle to the economic integration of food markets. One example is the delicate task of arbitration performed for decades by the Court of Justice of the (now) European Union in response to allegations of illegal restrictions in this area.

But diverse historical factors obliged a relaxation of this containment in the 1990s. A typical case is that of novel food, in other words, food-stuffs with limited market presence prior to the decade of the 1990s. Some states began the task of creating laws for these, while almost in parallel international regulatory mechanisms – some state based and others market based – would establish regulatory systems for these foods (especially for GM). As these are new products, the degree of entrenchment in the traditions and legal cultures of countries is lost, and it is difficult to counter the strength of laws created at supra-state levels. We are faced with competing regulatory regimes, which vary according to scale, economic base, legality, and to the attention they pay to health, safety, and the environment (Oosterveer 2007).

Regulatory Frameworks on an International Level

Since the aftermath of the Second World War – in some cases since before – some institutions committed to guarantee access to food, personal safety, the environment, or the development of peoples (FAO, WHO, UN, etc.). But in spite of their efforts, international governance of the agri-food sector has hindered by institutions like the WTO, which have exponentially multiplied what is regarded as the tradable character of food.

The WTO SPS agreement permits signatory states to establish sanitary or phytosanitary measures to obstruct international trade in their territory. But it limits these measures to those based upon the scientifically supported existence of risks to human, animal, or vegetable health. In those cases in which scientific backing is deemed insufficient, the WTO organs of appeal only admit provisional measures if these are interpreted as “reasonable.” Another significant agreement is the *TBT Agreement* (Agreement on Technical Barriers to Trade), which limits the possibility of establishing technical trade barriers such as the requirement of labeling, traceability, or special measures in transport. These types of measures, in order to be legal, must be justifiable according to their necessity or proportionality in relation to quality, food safety, or the prevention of unfair practices.

And What Happens Within States and Regions?

Some state models, particularly in Europe, are reluctant to accept food trade which to some degree fails to take into account concerns such as the environment, ethics, or consumer protection beyond basic food safety. Thus, they implement risk assessment models which not only address *unchallenged scientific evidence*, but which also, for example, adopt different formulations of the precautionary principle. In other words, they employ certain risk management guidelines even when the latter have been scientifically adjudged to be uncertain. There is also the introduction of principles such as that of case by case and step by step, which involve greater controls than those allowing recourse to principles such as familiarity or substantial equivalence.

Another aspect in which state models and those of some regions (like the EU) differ over what prevails in the WTO is the fact that in decision-making with regard to risks they do not restrict themselves to scientifically evaluating the latter. There is a risk management phase in which other criteria are also taken into account. Certainly, the principal criterion is the scientific assessment of risks, but in decision-making, certain other criteria are borne in mind, such as the economic impact of decisions (effects on production, on sales, the consequences of the unwanted spread of some crops) and, among others, consumer rights and interests.

The European Union regulatory model was forged early in the twenty-first century, once member states had accepted as a common reference the scientific criterion of the EFSA (created in 2002). This unique scientific criterion is just one of the steps in a process in which decision-making with regard to GM food and feed or functional foods also reflects criteria of another nature. This is the case, for instance, of (EC) Regulation 1924/2006 of the European Parliament and of the Council on nutrition and health claims made on foods. This Regulation establishes the creation of a single list of nutrition and health claims legally authorized for its use in the EU. This incorporation depends firstly on a scientific assessment

performed by the EFSA but is also directed towards average consumers properly understanding the claims addressed to them and not being disoriented in the appropriate composition of their diet. Note that this far exceeds what the TBT agreement of the WTO considers “necessary” on labeling.

Another case worthy of mention is that of Regulations EC 1829/2003 on genetically modified food and feed and 1830/2003 concerning their traceability and labeling. Without prejudice to the stringent processes for evaluating risk to human health and the environment, the only products authorized are those that are not disadvantageous in relation to their conventional counterparts. Labeling is required to reflect not only if this is GM food but also any other *ethical concern* that consumers may find relevant.

The Way in Which Contemporary Law on Food and Agriculture Research Is Critically Reviewed

None of the current trends in food ethics question the fact that food is much more than just a tradable commodity. And some of their proposals highlight the importance of questioning the model of food governance prevailing at a global level. Under the pretext of harmonizing *common* concerns regarding trading in agro-food products – basically food safety – the tradable character of food has been reinforced, as well as the significant deregulation of the market. Is it possible to reconstruct governance and place limits on such extensive freedom in the market?

It is also interesting to observe how this trend has influenced the evolution of food science and technology. Although in their early stages, small- and medium-sized companies participated in research into and commercialization of agrobiotechnological products, the complex legislative scenario has practically stripped the major life science corporations of competence. One might ask whether, perhaps for this reason, proposals of support for alternative food systems, compatible with a better

distributed socioeconomic development, tend to offer resistance to scientific and technological innovation. Have innovations in food and agriculture led to this global food system, or are those who have misused these innovations the ones to blame?

After all, for centuries food and agricultural innovation have been accepted to confer competitive advantages upon those who control their trade. This does not seem compatible with fairness, sustainability, and all human beings enjoying access to food appropriate to their needs and desires. Yet, redirecting these scientific and technological advances towards respecting contemporary values is not a matter of technology regulation. It is perhaps time for humankind to decide if accepting the tradable character historically given to food is still adequate. The search for alternatives must also consider whether those who control the market should also dominate food governance.

Summary

This entry analyzes the ethics behind historical and contemporary food and agriculture law. Contemporary food law systems are very complex systems relating to a multitude of aspects of the production, distribution, and consumption of food, but to a certain extent, they share a common root with the food law that was already operating in ancient Rome. Humans do need food to survive, but that has not been considered a key issue for the food law. For centuries legal mechanisms have considered food as a tradable commodity, and this trend has also influenced the evolution of food science and technology. The main characteristics of contemporary laws and regulatory mechanisms on food and agriculture research are presented here as well as the way in which they are critically reviewed.

Introduction

Food's presence in novels, poems, drama, and literary essays is about more than a realistic depiction of everyday human existence. Literary scholars and anthropologists alike agree that food acts like a language, communicating between cooks and eaters, authors and readers. In literary texts, then, food forms a second layer of signs that reflect and sometimes complicate the words on the page. "Food is endlessly interpretable," asserts the literary theorist Terry Eagleton (1998, p. 204), and anthropologist Carol M. Counihan explains why: just like language, "food is a product and mirror of the organization of society on the broadest and most intimate levels" (1999, p. 6). Food, with its ability to reflect social organization and bear endless interpretation, is an ideal tool for literary authors: a language of symbols within a language of words.

All cultures use food as a means to distinguish among categories of people (Counihan 1999). Different foods and food-related practices indicate membership in different classes, castes, races, and gender categories. Yet food has a special relationship to sex. Like sex, food is a biological necessity, but the acts associated with it are loaded with social meanings (Douglas 1999). Moreover, like sex, food brings what is outside the body into the body, and like sex food initiates a physical union with the outside world (Counihan 1999). Thus, food can represent the penetrability and penetrative capabilities of the human body, its ability to absorb and dominate others, and the body's

capacity, as mere matter, to be subsumed and controlled by others. Given the metaphorical as well as social links between food, gender, sex, and language, food becomes a highly effective way for literary authors to depict and explore gender roles in their work. The purpose of this entry is to examine the ways that literary authors use food and the practices related to it to depict both normative and non-normative modes of performing gender. In the texts discussed below, food symbolizes the relationship between characters and their own gendered bodies, and makes visible the social exchanges that occur between characters. This entry will discuss authors' frequent association of particular foods with male and female genders in English and other literary traditions, as well as the gendered associations of serving, cooking, and eating food for men and women. Finally, it will examine the use of food in some literary texts to depict characters' resistance to normative gender roles, concluding that in some texts, to defy normative practices of eating, cooking, and serving is to defy the utility of the gendered codes that determine what it means to be an ethical agent in one's community.

Reading Food's Gendered Implications in Literary Texts

A scene from the British comedy *The Country Wife* (1701), by William Wycherley, shows how food can function on multiple levels of meaning to expose social and sexual tensions in a literary text. In Wycherley's play, the seductive Mr. Horner treats Marjorie Pinchwife to a basket of oranges, an imported and relatively expensive fruit at this time. When Marjorie's husband, Mr. Pinchwife, finds out what Horner has done, he responds angrily. Mr. Horner protests: "I have only given your [wife] an orange, sir!" (3.2.598), "Only squeezed my orange, sir," replies Pinchwife, "and given it me again" (3.2.599-600). In this exchange, food means at least two things: the orange is "only" an orange – mere matter to be eaten and expelled – but it also symbolizes the body of Marjorie Pinchwife, "squeezed" by

Horner, and therefore rendered sexually useless to her husband.

Although the orange in this scene represents a sexual exchange as well as an edible treat, it is important to emphasize that there is no universal code by which an orange, or indeed any other food, can be interpreted. The orange that symbolizes adventure and sexual transgression in Wycherley's *The Country Wife*, for example, carries an almost opposite connotation of banality and social conformity in Jeanette Winterson's novel *Oranges Are Not the Only Fruit* (1985) – a connotation that depends in part on the much lower cost and greater availability of oranges in the mid-twentieth century as compared to the 1700s. An orange might symbolize monstrosity in one text, because citrus fruits were notoriously difficult for early horticultural scientists to classify (Freedberg 1992), or it might stand in for the fruits of Eden in the biblical book of Genesis as it does in Andrew Marvell's 1653–4 poem, "Bermudas" (Deutsch 2009). Instead of attempting to decipher the universal meanings of foods across all texts, this entry deals almost exclusively with texts in the British and North American literary traditions, recognizing that as a reflection of the cultures in which food is eaten, written, and shared, food's meaning depends heavily on context.

Masculine and Feminine Foods in Literature

Food has no universal code (Douglas 1999). Still, literary critics and anthropologists have ventured a few generalizations regarding the foods more often associated with women or men. Tomoko Aoyama writes that "while meat and offal tend to be categorized as masculine food in many cultures, sweets are usually considered feminine" (Aoyama 2008, p. 172), a division that the activist and author Carol J. Adams analyzes as symbolic of men's social power over both women and other animals (Adams 1990). Indeed, scenes of meat eating are frequently mobilized in literary texts to represent male characters' relationship to the power accorded them through their gender,

especially power over women. In her fictional book *Sociable Letters*, the sixteenth-century author Margaret Cavendish describes a fight between a wealthy knight who loves beef and his wife, who thinks beef is a disgusting and unfashionable dish. When the lady C.C. orders a fashionable feast, the family cook, "knowing his Master loved ro[a]st beef," chooses to defer to male authority and serves a joint of beef. The knight and lady throw food and come to blows over the dish, but throughout this scene, beef represents the enduring power of both the "old country fashion" and the Master's power with which it is associated: "all the fine Quelquechose was overthrown in the hurly burly, but the Beef was so Substantial and Solid, as it strongly kept its place" (Cavendish 1997, p. 45). The beef – a type of meat that was already steeped in associations with the power of the British landed class (Thirsk 2007) – then comes to represent Sir G.C.'s power over both his wife and his household.

In the letters of Margaret Cavendish, men are associated with the strong, substantial qualities of meat. Women in literary texts are also associated with meat; however, they are more frequently identified with the materiality of meat: its deadness, its exchangeability, its submission to the knife and jaw. This idea of women as edible is both old and widespread. Counihan notes a strong relation between women and food in general, across all societies, and she attributes this association primarily to women's reproductive capacities: "Women *are* food to the fetus and infant," notes Counihan, so that across cultures, "although women's feeding activities are undertaken with widely ranging amounts of autonomy, prestige and control, they are nonetheless universally linked to womanhood" (Counihan 1999, p. 63). Thus, foods associated with animal and plant reproduction, notably milk, eggs, and fruit, are often also foods associated with women's bodies and sexuality. In some cases foods represent the female body itself, especially its fertility, power, and physicality: in the novel, *Bailey's Café*, one character symbolically enacts the labor of another by cutting the pit out of a ripe plum (Naylor 1992), and in the 1959 play *A Raisin in the Sun* by Lorraine Hansberry, the character Ruth

Younger feeds her husband scrambled eggs that foreshadow Ruth's decision to abort the child she is carrying (Matthews 2008).

In a device that is mimetic of the discharges of child birth and sexual arousal, women in literary works also sometimes drip or leak as a sign of their excessive consumption of food and sex, and these uncontainable liquids reflect the fear that women's sexuality cannot be disciplined to desire only within the boundaries of designated social institutions such as marriage (Kowaleski-Wallace 1997). In Christina Rossetti's poem *Goblin Market* (1862), for example, eating the fruit of "goblin men" (l.49) is a sexual initiation into "joys brides hope to have" (l.314). The young girl Laura trades a lock of hair for the chance to "suck[] their fruit globes fair or red" (l.128), but when she is denied more fruit, she trudges home, "her pitcher dripping all the way" (l.263). The squeezed orange that is Marjorie Pinchwife and the dripping pitcher that is Laura are both symbolic of these female characters' unruly flow toward men they haven't married, and many other texts depict women who are literally overflowing with sexual energy and excess food. Petal Bear, a character in E. Annie Proulx's novel *The Shipping News* (1993), overflows with both: the novel's narrator reports that 4 days after giving birth, Petal "hauled a dress that wouldn't easily show stains over her slack belly and her leaking breasts and went out to see what she could find" (p. 14). In Thomas Middleton's play *A Chaste Maid in Cheapside* (1613), written almost four hundred years earlier, the out of control women celebrating the birth of Master and Mistress Allwit's newest child gossip and gorge on sweets and alcohol until their bodies can hold nothing more: Mistress Allwit bears a daughter, while the rest of the women wet their seats (3.ii.220).

Cooking and Serving in Literature

As social exchanges, the practices associated with preparing and serving foods are perhaps even more reflexive of gendered social relations than are foods themselves. In British and North

American literary traditions, the most positive representative of femininity and the soundest ethical agent is usually the woman who serves food to others instead of eating it herself. Likewise, a female character's refusal to prepare and serve food to others is often paralleled by other antisocial and non-gender-normative behaviors such as greed for power, violence, and unbridled sexuality. *The Shipping News* (1993), contains an example of each kind of woman. Set in the late twentieth-century Newfoundland, Canada, the character Beety Buggit's homemade bread and tea are part of a communal effort to morally and spiritually recuperate the novel's male main character, Quoyale. The narrator notes that Beety's home contains not one but two tea kettles, each one constantly kept hot (p. 137), and her husband reports that "Beety makes bread every day" (p. 101). The tea and toast of the Buggit house stand in stark contrast to the "never-used pot" (p. 23) and "sandwich cheese, streaked with green" that the novel associates with Quoyale's depraved ex-wife, Petal (p. 14). For Petal, the failure to nurture her family through food extends to other moral failures. She is a "bitch in high-heels" (p. 24) who cheats on her husband and tries to sell her two daughters into the sex trade. Her failure to nurture through tea and sandwiches in the kitchen parallels her failure to nurture in any other context, while the two raw eggs she gives to her husband one Christmas symbolize the two daughters she bears to Quoyale (p. 307). Just as Quoyale has to cook the eggs himself, he must raise the two girls on his own.

Scenes of women serving in literary works often acknowledge the power inherent in women's control of the kitchen. In *Like Water for Chocolate* (1992), a novel by Louise Esquivel, the main character, Tita, cooks for Pedro, the man she loves but is not allowed to marry, and the dishes themselves are experiences of physical intimacy akin to sex. Through them, Tita enters Pedro's body, so that normative sexual roles are reversed. Eating Tita's food, "Pedro didn't offer any resistance. He let Tita penetrate to the farthest corners of his being" (p. 52). Power in the kitchen, however, is tinged with danger: women who introduce the wrong foods into the bodies of their

culinary dependants act as agents of incoherence within their family systems. In Tobias Smollett's novel *The Expedition of Humphrey Clinker* (1771), for example, the dining table is the center of dysfunction in a British upper class house. The food Mrs. Baynard provides is "contrived...without one substantial article adapted to the satisfaction of an English appetite" (p. 295) and is one facet of the "cold, comfortless, and disgusting" habits of conspicuous consumption in her household. Poor eating has "preyed upon" her husband's health, so that his wife seems to be consuming her husband through the very food she serves him (p. 290).

Men's cooking in literary texts, like their association with meat, often reflects a cultural expectation of mastery over their bodies and the outside world. Male cooks, notes Aoyama, are the culinary artists and "celebrated chefs" of the professional cooking world, while "women...are expected to take charge of the much less glamorous, unpaid work of everyday domestic cooking" (2008, p. 172). This distinction often holds in literary texts as well. Aoyama analyzes a series of modern Japanese works where men occupy a position of authority in the kitchen, teaching daughters or mistresses to cook the food they like (2008). Likewise, in *Sorry Fugu* (1989), a short story by the American author T.C. Boyle, a chef afraid of bad reviews from a young female restaurant critic reeducates her taste in an erotically – charged scene where he places buttery squid rings in her mouth with his own fingers (p. 17). For both male and female characters then, scenes of cooking and feeding in literary texts are struggles for power over and access to the body of another person. Women's cooking is usually positive, but only if it is directed toward the nourishment and service of male bodies. Men's cooking and serving, on the other hand, in general bears positive associations only when it can be viewed as an expression of mastery, either over the skill of cooking or over women who must be taught to correctly prepare and enjoy food. Quoye's response to Petal's raw eggs is a case in point. He makes an omelet of them and hand-feeds it to his wife "as if she were a

nestling bird," an act that *The Shipping News* depicts not as meaningful nurture but as a symptom of Quoye's "pathetic" self-hate (p. 307).

Eating, Food Refusal, and the Gendered Contexts of Self-Control

For both male and female characters in literary texts, self-regulation of one's appetite is a positive sign of self-control. Especially for female characters, the choice to refuse food, even to the point of starvation, can signify a character's manipulation or even transcendence of the networks of social and sexual exchange that control them, while for male characters, mastery of the appetite symbolizes the self-mastery necessary for participation in the public sphere.

This entry has addressed the ways in which foods can symbolize sexual penetration because of food's capacity to traverse the boundaries of the body. This metaphorical parallel makes food refusal an especially symbolic action for characters whose bodily autonomy has been explicitly violated through rape or abduction. In such scenarios, authors sometimes use the refusal to eat as their characters' last bastion of control. Perhaps the best-known example of this kind is *Clarissa Harlowe*, the heroine of Samuel Richardson's eighteenth-century epistolary novel *Clarissa* (1747–8). Self-starvation in *Clarissa* leads to transcendence of an unequal and disempowering patriarchal power structure, and self-denial is framed as self-determination (Ellman 1993). After being raped by her former suitor, Robert Lovelace, who has kidnapped and drugged her with a cup of adulterated tea, *Clarissa* symbolically closes the borders of her body, refusing to allow any sustenance to pass across the boundary of her mouth. She starves herself to death in order to gain release from the brutal and tyrannizing power that the men in her life – including her father, brother, and uncles as well as Lovelace – have exercised on her body. In the end she is a "lovely skeleton" (p. 1231), and Richardson implies a correlation between the thinness and lightness of her body and the density and intensity of her spirit and her faith in god.

Masculine Self-Control and Political Participation

Self-control in relation to food is linked to bodily autonomy for male characters as well. In many texts men's gustatory self-control is a basic requirement for the right to own property and participate in civil discourse. In Henry David Thoreau's series of biographical essays, *On Walden Pond* (1854), for example, the author associates political autonomy with control over his own food supply when he provides detailed descriptions of the production and processing of a field of beans that he will eventually harvest and trade for other food. As he works, Thoreau hears the sounds of military exercises in the distance and links "the liberties of Massachusetts and of our fatherland" (p. 205) to his own labor in the field. Though Thoreau doesn't eat the beans himself, they allow him to master his own food supply, assuring that the basic needs of his body are met. Thoreau links this bodily integrity – his ability to exchange his own labor for his own body-sustaining food – to the quest for intellectual and political autonomy that brought him to Walden Pond in the first place. He views the bodily autonomy he gains through exchanging his own labor for food as more valid than the purely intellectual autonomy pursued by "my contemporaries devoted to the fine arts in Boston or Rome" (p. 207).

For African-American male characters in the novels of Gloria Naylor, food figures the enormous social pressures under which non-white men operate in the public sphere. For Naylor's men, the right to participate in the almost exclusively white world of business in the twentieth century can only be achieved through the most extreme acts of bodily self-control. In the novel *Linden Hills* (1985), an African-American business executive, Maxwell Smyth, finds that being "always immaculate and controlled" makes his race disappear in the eyes of others (p. 103). He polices his own diet with such minute attention that he no longer needs to defecate, since, "through a careful selection of solids and liquids, he was able to control not only the moment but the exact nature of the matter that had to bring him

daily to that blue and white tiled room" (p. 105). In Naylor's novels, as in Thoreau, controlled consumption is part of the performance of normative masculinity and is a necessary adjunct to participation in civil and professional life. For the men in Naylor's novels, however, the labor required to force the black male body to appear as normative is a complex and potentially self-destructive undertaking, one that eventually, as in *Clarissa*, makes the body wholly disappear. Again, this self-destruction is symbolized through food: a quickly – warming glass of whiskey on the rocks symbolizes the way in which Maxwell's apparent mastery of bodily integrity will lead, paradoxically, to the disintegration of his sense of self – rigid ice cubes melt into the brown whiskey, weakening it, and Naylor writes that, "very soon, there would be nothing but a mouthful of watery bourbon that could be gotten rid of in a single swallow" (p. 111).

Queer Food

Refusing to eat, serve, or cook in gender-designated ways is a sign that a character refuses to abide by the social system in which they are enmeshed. Where the offending man or woman is punished, the literary work might be said to take a conservative approach to the relationship between gender, food, and ethics, as, for example, in the case of Petal Bear, the depraved wife of Quoyle in *The Shipping News* (1993), whose gender non-conformity, expressed in part through her refusal to cook for her family, is definitely unethical and is punished accordingly by a violent death (p. 24).

But not all novels punish non-gender-normative relationships to food or associate them with unethical behavior. Refusing to eat according to the rules can be a powerful symbol of bodily self-determination for queer and other non-gender-normative characters. In Alison Lee's short story *A Lesbian Appetite* (2002), the narrator insists that "healthy food" is the food of sex and pleasure (p. 170), whether that means eggplant or red velvet cake. Although teachers, doctors, and manipulative lovers try to feed the narrator food that they claim is morally and

nutritionally superior, the value of food in this story is explicitly in the social relations that it enables. Cooking, eating, and lovemaking are linked in that all require sensuality, respect for the body, and reciprocity in order to be good for you.

Subverting the connection between dietary self-control and political personhood, Sherman Alexie's short story *What You Pawn I Will Redeem* (2003) critiques the idea that men who eat and drink to nauseous excess are unworthy of self-determination and property ownership. The story follows Jackson Jackson, a homeless Spokane man who describes himself as "an alcoholic Indian with a busted stomach" (p. 178). After finding his grandmother's powwow regalia in a Seattle pawnshop, Jackson has between lunchtime and lunchtime to earn the \$999 he needs to buy it back. Instead, Jackson spends his money on liquor and McDonald's hamburgers that he promptly vomits up again. Drinking excessively, getting something for nothing, disrupting traffic, and dancing in a woman's clothes, Alexie's character defies the relationship between controlled consumption of foods, proper performance of gender, and social participation. What should be abjecting, antisocial, punishable behavior, however, results instead in reward: Alexie's character gets his grandmother's rain dance costume returned to him, and the story refuses to represent as natural the symbolic connection between men's gustatory self-control and their personal and political autonomy. The fact that this story relies in part on magical realism – the pawnshop is never in the same place twice – underscores how unusual its depiction is of a world where the good guys can eat and drink until they vomit without giving up their status as ethical agents.

Summary

Literary texts use food to represent and reflect on social practices around gender. While food is highly symbolic, foods are not universal symbols and must be interpreted within the historical and cultural context of the literary work in which they are found. Focusing especially within the British

and North American Literary tradition, however, this entry draws some broad conclusions: women, who are associated through food with reproduction and nurture, must cook for and serve food to others in order to read as ethical agents. Conversely, women who refuse to cook are generally depicted as antisocial. Men's relationship to food reflects an expectation that men hold social and sexual power over others. Thus, men's association with meat reflects male power over women and animals. Moreover, men are required to control their own diets and the diets of others in order to qualify as autonomous individuals and participate in public life. This entry also examines the ways in which some texts resist these normative relationships between food and gender. Some works discussed here expose the unsettling fact that self-starvation may be a female or black male character's only means of gaining bodily autonomy, while others dis sever the links between uncontrolled eating and antisocial behavior for people of any gender.

Synonyms

Animal rights; Frozen meat export; Halal and kosher slaughter and stunning; Live animal exports; *M.V. Cormo Express*; Trade-offs between animal welfare and economic considerations

Introduction

The ethical issues raised by the live farm animal export trade are framed by conflict between animal welfare and economic considerations. On the one hand, live farm animal exports are big business. The Australian industry, the world's largest, employs around 13,000 people and in 2015 exported just under a million cattle worth A\$1.06 billion dollars and 1.4 million sheep worth A\$190 million dollars (MLA Statistics Database; Hassall and Associates 2006). On the other hand, the trade poses significant threats to animal welfare. Cold weather killed around 15,000 sheep in a Victorian feedlot prior to boarding in 1983; more than 40,000 sheep drowned when the *Farid Fares* sank in 1980 (Georges et al. 1985, pp.5–6); and nearly 6,000

died in 2003 when the *Cormo Express*' 15-day trip extended to 80 days (Keniry and Australian Department of Agriculture, Fisheries and Forestry 2004). In 2011 the Australian *Four Corners* television documentary, "A Bloody Business," exposed shocking animal mistreatment in Indonesian abattoirs (ABC 2011). Export bans introduced in response to the documentary were said to have left 13,000 cattle stranded on Australian wharfs and graziers with 150,000 other beasts which, it was claimed, would have to be shot or set loose on the rangelands of northern Australia if not exported, leading to "starvation ... on an unprecedented scale and an environmental catastrophe ... that will take 100 years to recover from" (SMH 2011).

Some ethical objections to live export reflect broader concerns about agriculture and the treatment of farm animals. Someone who regards the raising and management of animals for food and produce as unethical will also regard the live export trade as unethical. Other ethical concerns are motivated by features that are more or less distinctive of the trade. This entry addresses concerns of the latter sort and so assumes, for the sake of the discussion, that it is ethically legitimate to raise animals for food and produce and treat them according to standard agricultural animal welfare models that support those practices.

Focus on the distinctive features of the live export trade still leaves a broad and complex practice for evaluation: The "live animal export chain," the journey taken by an exported animal, has many links. It may be regarded as beginning when farmers produce animals in response to export incentives or when animals destined for export are mustered on farms in exporting countries. Those animals are transported (sometimes long distances (Fisher and Jones 2008, p. 325)) to export ports, conditioned to the food that will sustain them during their journeys, embarked, transported by ship or (in smaller numbers) air, disembarked, managed at their destination ports, transported, to farms if they are intended to add to local herds or flocks or more or less directly to slaughterhouses, or more or less directly to slaughterhouses, managed prior to slaughter, and, finally, slaughtered. As the litany of mishaps above illustrates, every step of the chain, from the production of stock for the trade

through to slaughter in importing countries, has generated issues relevant to the ethical evaluation of the trade.

Rights and Trade-Offs

One might think that animal welfare considerations should "trump" competing economic considerations, that they should be regarded as "rights," where, as a conceptual matter, rights give reasons to treat their holders in certain ways even if some social aim would be served by doing otherwise. In practice, the welfare interests of animals have not been regarded as absolute constraints on the live export trade, but instead as considerations to be weighed in a balance with other factors. A 1985 Australian Senate Committee concluded that "if a decision on the future of the [live sheep] trade were made on animal welfare grounds alone, there is enough evidence to stop the trade" but went on immediately to "acknowledge[] the reality of the situation" that the decision would not be made on animal welfare grounds alone and the trade would continue albeit, they recommended, under improved welfare regulation (Georges et al. 1985, pp. 185–186).

There are a couple of conceptual matters to note here. First, one cannot deduce from such remarks that animal welfare interests are not regarded as "rights" in this context. The Senate Committee clearly thought animals did not have determinative rights not to be subject to the live export chain, but their view – and their insistence on improved regulation of the export industry – is consistent with the belief that the animals had other rights, perhaps to have their welfare interests taken into account in the design of export trade regulations. Such rights would entail that animal welfare interests could not legitimately be disregarded in that process, even when doing so would serve some other interests. The general points are that the normative significance of rights depends upon their content and that some rights fill roles within broader practices that allow balancing and trade-off. Second, the term "animal rights" need not refer to rights held by animals *themselves*. It may instead describe rights held by humans, the content of which bear

primarily or solely on animal welfare. In this sense animal welfare regulations place duties on those who exercise control over animals, duties which are correlative to rights held by those persons who can demand, as of right, that human duty holders exercise their duties. The actual and intended beneficiaries of such rights are animals even though the rights holders are human. This conceptual account of the content and role of animal rights will seem unsatisfactory to many animal rights advocates, but important human rights work in the same way, requiring proper regard to a person's interests in decision procedures (even procedures which may result in execution), and such rights, whether human or other animal, are not vacuous. They can impose genuine and meaningful obligation and constraint.

It seems clear that animals do have (conventional or institutionally bestowed) rights of at least this sort and that those rights matter in the live animal export trade. Balancing and trade-offs may be ethically permissible, but the human holders of rights designed and intended to benefit animals can insist, as of right, that such accommodations have proper regard to animal welfare interests. That means, at least, taking the provisions of conventional animal welfare regulations seriously, and it may mean rather more than that, requiring that the human interests which are served by the export of live animals are of sufficient importance to justify the inevitable suffering export will impose on animals. Our standard agricultural practices rest on the belief some human interests do warrant the imposition of some suffering on animals but taking animal welfare interests seriously entails that not *every* human interest – perhaps a purely aesthetic preference for fresh meat (Davies 1986, p. 151) or to avoid a marginally less profitable use of land or means of transporting animals – is taken to warrant *any* amount of suffering by exported animals.

If We Don't Meet the Market, Someone Else Will

Defenders of the live export trade from particular countries sometimes argue that stopping the trade

from that country will do nothing for animal welfare since importers will simply buy livestock from another supplier. If true, the loss on the economic side of the balance for desisting exporters will not be offset by animal welfare gains; the burden will simply shift from some animals to others.

There is a tempting response to the simplest version of the argument. *If* live exporting is wrong, then the fact the practice would continue, supported by another wrongdoer, cannot of itself justify continued wrong doing. Demand for narcotics is probably ineliminable, and there are suppliers waiting to take over from any current wrongdoer who reforms, but that hardly seems to excuse pushers. If no one should engage in a trade, the fact some people do should lead us, not to join them, but to remonstrate with them (Davies 1986, p. 153).

Perhaps unsurprisingly, however, the “if we don't, someone else will” argument is rarely put in this simplest form. It is normally supplemented with claims that the withdrawal of a current exporter will lead to an overall deterioration in, or to the loss of an opportunity to improve, overall animal welfare. The “deterioration” form of these supplementary claims maintains that importers will begin to trade with suppliers who will treat exported animals *worse* than the withdrawing exporter. When Australia banned shipments to Indonesia following the *Four Corners* documentary, for instance, opponents argued that Indonesia would buy cattle from Malaysia or Brazil, both countries, it was claimed, with worse animal welfare practices than Australia. The animals shipped to Indonesia from those countries would suffer more than those shipped from Australia (if only because of the longer journey from Brazil), and, therefore, Australia would prevent greater harm to animals by continuing to export. The “improvement” form of the supplementary claims maintain that the current exporter's continued involvement is likely to bring about an improvement in animal welfare, rather than simply avoiding deterioration. Live export advocates contend, for instance, that Australia and New Zealand have higher animal welfare standards than some potential importers and that, if they are exporting to those countries,

they are in a position to bring about animal welfare improvements in those markets.

Both of these supplemented forms of the “if we don’t, someone else will” argument are conceptually more plausible than the simple original. Going back to the analogy with the narcotics supplier, one might see the responsible exporter occupying the same role as a pharmacist distributing methadone as part of a rehabilitation program. She would rather not supply narcotics at all, but she thinks that if she does not someone else will, that addicts are safer dealing with her, and that her involvement provides an opportunity for her and others involved in the program to encourage users to reform.

It is important to see an ethical limitation of the deterioration form of the supplemented argument. The fact an alternative supplier will treat animals worse than current exporter does seem to provide a reason not to withdraw from a practice one is certain will continue, but the argument seems to allow an existing exporter to calibrate their animal welfare standards to a level just better than the next-best alternative. Provided such an exporter does so, they will be able to say that they have a reason not to withdraw since if they do so, animal welfare will slip to the level maintained by their slightly worse competitor no matter how bad that competitor’s welfare standards are. That suggests, at least, that this form of the “if we don’t, someone else will” argument will not itself address concerns about the welfare of exported animals.

The second form of the argument, which rests upon the potential of existing exporters to *improve* animal welfare standards in importing countries, does slightly better on that score, though it too could provide a reason not to withdraw if *any* potential improvement from a perhaps very low animal welfare baseline could be bought about by a current exporter but not by their next-best competitors. The improvement form of the argument might give reasons to continue exporting, that is to say, provided a current exporter could secure relative but not significant improvement in animal welfare in importing countries.

In practice, however, the improvement form of the argument is typically linked to the animal welfare standards of exporting countries, and, so

linked, it appears to be more promising. If we accept that agricultural animal welfare standards in, say, New Zealand and Australia, are for the most part ethically defensible and if we think that exporters from those countries could within some reasonable time see *those* standards implemented in importing countries provided they remain involved in the live export trade, then this form of the argument gives grounds not only for continued involvement but also for significant rather than merely relative improvements in animal welfare.

Of course the proof will be in the (black) pudding. The force of these arguments rest on the will and capacity of exporting countries to effect genuine improvement in animal welfare conditions in importing countries. Opponents of live export are skeptical. Exporters, they argue, have little say over conditions outside of a few controlled abattoirs; there is little sign of improvement in animal welfare conditions in importing countries despite decades of trading with higher animal welfare suppliers; and it is possible, they fear, that continued trading signals international approval of local standards, entrenching rather than modifying those standards.

Export Livestock or Carcasses?

It has seemed to many that there is a straightforward compromise between the welfare and economic considerations that frame the live export debate. Exporters, it is suggested, should satisfy importers’ demand for meat by sending the frozen carcasses of animals slaughtered in exporting countries. Exporting carcasses would eliminate the burden of long journeys and preparation for them, allow exporting countries to manage and slaughter stock according to their own welfare standards while also preserving a market for farmers and others currently reliant upon the export trade.

As an ethical objection to the live animal export industry, the proposal to replace export for slaughter with exported carcasses rests on the argument that the suffering of animals exported live is unwarranted since the interests by reference

to which it is justified can be achieved with equal efficiency without that suffering. So stated, the argument turns on the largely empirical claim that carcasses *would* meet the interests currently met by live export.

Some of those interests would obviously *not* be met by carcasses. New Zealand banned export for slaughter following the *Cormo Express* debacle, for instance, but still allows live export for breeding and production, and under that policy exported almost 86,000 dairy cows to China in 2014 and 50,000 sheep to Mexico in 2015. Carcasses could not replace these live exported animals. The not-for-slaughter live export chain shares many of the links with its for-slaughter counterpart and so raises some of the same ethical issues. Export numbers might be expected to fall, however – the New Zealand sheep export to Mexico was unusually (critics thought suspiciously) large (NZH 2015) – and perhaps there is a greater incentive and capacity to protect the welfare of typically smaller flocks and herds, which will be of use only if they arrive in good condition and thrive for some time thereafter.

Still, the live export trade purports to address interests that would not be met by carcass exports.

At the export end of the chain, the impact of ending live exports for slaughter would vary from country to country and state to state within countries, depending upon current reliance on the trade. New Zealand seems to have been relatively unharmed by banning export for slaughter – indeed in 2015 meat industry figures said New Zealand has “too much to lose by allowing the resumption” of the trade (Hutching 2015) – but Australia’s meat industry is much more heavily structured around the live export industry, and currently not-for-slaughter exports are a tiny part of that country’s live export trade. The economic significance of the live export trade for Australia, however, is contested. Meat and live animal export industry-commissioned reports estimate that the Australian livestock export industry was worth \$4.19 billion between 2001 and 2006 and forecast falls in sheep and cattle prices of up to 18 % and 7 %, respectively, if competitive support for domestic prices provided by live export were to end (Hassall and Associates

2006). A report commissioned by the Australian meat processing industry paints a very different picture. It argues that phasing out live sheep exports would have minimal impact on farmers and reap long term benefits through increased processing in Australia, that the live export trade competes with potentially more or equally lucrative frozen or chilled exports, that live export is profitable only because it is subsidized and protected, and that it is destroying the valuable domestic beef industry in some states (Heilbron and Larkin 2000).

This dispute as to the value of the live export trade goes directly to the question whether the interests met by the export for-slaughter industry would be equally well met by a carcass export industry. These matters cannot be settled here, but note that if the economic concerns are finely balanced or even marginally in favor of export for slaughter, there may still be ethical grounds to prefer carcass export. The sacrifice of animal welfare interests requires significant benefit to humans, and so animal welfare advantage gains might warrant the sacrifice of marginal economic benefits. If the benefits of live export for slaughter are marginal, it may be incumbent upon exporters to bear the cost of taking animal welfare interests seriously.

The live export industry also meets interests at the import end of the export chain. Would carcasses meet those interests?

Some importer interests will have greater weight than others. If “importers’ preference for fresh meat is merely aesthetic (as opposed to being required by prevailing custom, religion, or circumstance), one ought to rightly balk at meeting the importers’ demand for fresh meat” (Davies 1986, p. 151). Meeting such interests would not warrant very much animal suffering.

Other interests appear more substantial. Exporters sometimes suggest that live exports, slaughtered close to the point of consumption, sometimes meet genuine and important interest in access to safe food because of poor access to refrigeration and modern retailing facilities. However, circumstances are changing. The meat industry itself recognizes increasing consumer wealth and the growth of modern retailing

facilities in its target markets. They remark that Bahrain's "retail sector is rapidly growing more sophisticated, and more open to cryovaced chilled product" (Cawood 2014), and they could equally well have been speaking of Indonesia or Egypt. Increasing consumer wealth and changes in retailing in importing countries seems likely to reduce the significance of slaughter close to consumption, at least on these food safety grounds.

What of religious or cultural reasons to prefer live exports? A long-standing justification for live export has been importers' interests in halal or kosher (shechita) slaughter, required by some Moslem or Jewish consumers, which is often said to prohibit the stunning of animals before slaughter, a practice widely promoted on animal welfare grounds and which has genuine and measurable animal welfare advantages: brain scans detect pain signals lasting for up to two minutes following throat cutting without pre-stunning. When the animals are concussed through stunning, brain signals corresponding to pain disappear (Gibson et al. 2009).

There is some dispute whether halal slaughter does prohibit stunning. The New Zealand position is that halal slaughter requires only that the animal actually dies from the "halal cut" to the throat, that is, that the preslaughter stun is not lethal (MIA 2014). There is, then, no exemption from requirements for preslaughter stunning in New Zealand halal-certified slaughterhouses. Most halal slaughter in Australia does involve prior stunning, though a small number of abattoirs are permitted to conduct religious slaughter without prior stunning. The UK does provide a general exemption from stunning on religious grounds though it is estimated that 84 % of halal-slaughtered animals are stunned (RSPCA 2015). It appears to be more widely accepted that kosher slaughter does prohibit pre-stunning.

The situation, then, is complex. For the current discussion, the question is whether export for slaughter might be justified if the export of carcasses would not meet genuine religious and cultural interests in forms of slaughter that compromise animal welfare. Religious or cultural interests are not purely aesthetic: they matter to people in a way mere preferences do not.

Recognizing that importance does not require us to take a view on the whether any particular religious or cultural view is correct: we need only note that people's religious or cultural views often have deep and broad significance in a way other views do not. Some people may have been disappointed when Pluto lost its status as a planet, but the news is likely to have few implications for the way they understood themselves, the world, or their place in it. Religious or cultural views often do have that sort of broad significance, and that is in itself a reason to accord them special respect.

If genuine and important cultural interests could be met *only* by live export, those considerations would provide some justification for the trade. However, the conditional "if" needs to be taken seriously. If such slaughter is suboptimal for animals, the cases in which it is tolerated should be minimized, and if halal or kosher slaughter could be conducted in exporting countries (and the evidence suggests that it can be (Cawood 2014)), then it should be.

Conclusion

The live animal industry poses a set of distinct ethical concerns, framed by conflict between animal welfare and economic considerations. The effort to find an ethically defensible balance between those concerns requires regard at least to the nature and role of animal rights (whether held by animals themselves or by humans and whether they allow any trade-offs, for instance); to the significance of the presence of alternative suppliers – the "if we don't meet the market, someone else will" argument – often used to justify continued involvement in the trade; and to whether significant interests, including economic, cultural, and religious interests, are met by live animal exports which would not be met by the export of carcasses. The live export trade will be ethically justified only if it meets interests which cannot be otherwise met and which are sufficiently important to outweigh the significant and predictable suffering the trade imposes on animals.

Introduction

Local and regional food systems, sometimes referred to as “community food systems,” are collaborative networks that integrate sustainable food production, processing, distribution, consumption, and waste management in order to enhance the environmental, economic, and social health of a particular place. These networks reflect growing public interest in restoring the vital connections between agriculture, food, environment, and health. Local and regional food system networks engage a wide range of community partners

in projects to promote more locally based, self-reliant food economies. Particular community projects and strategies vary, but most collaborations seek to increase resident participation to achieve one or more of the following goals (UC SAREP website: <http://www.sarep.ucdavis.edu/sfs/def>):

- A stable base of family farms that use sustainable production practices and emphasize local inputs
- Marketing and processing practices that create more direct links between farmers and consumers
- Improved access by all community members to an adequate, affordable, nutritious diet
- Food and agriculture-related businesses that create jobs and recirculate financial capital within the community
- Improved living and working conditions for farm and food system labor
- Creation of food and agriculture policies that promote local or sustainable food production, processing, and consumption
- Adoption of dietary behaviors that reflect concern about individual, environmental, and community health

While no local and regional food system can claim to fully embrace or embody all the articulated goals, this framework provides an animating vision that spurs and sustains local action. Pursuing diverse goals simultaneously creates a host of practical and ethical challenges. These challenges, described more fully below, include (1) finding price points that work for farmers while ensuring low-income consumers have access to healthy food and food system workers have decent wages and benefits; (2) confronting racial and class bias while forging practical solutions; and (3) reconciling the desire to stay true to deeply held values with the need to compromise in order to achieve incremental changes (Campbell et al. 2013). Negotiating trade-offs among various goals and competing values is integral to this public work.

History of the Local and Regional Food System Idea

The attempt to be holistic in conceiving and pursuing local food system work is intentional. It stems both from the effort of local communities to solve interconnected problems (rather than treating them in isolation) and from a desire to consider multiple values in designing food and agricultural systems, rather than elevating a single value – economic efficiency – above all others. Local food system promoters consider agriculture, food, health, and environment as interrelated aspects of a single system whose overall health requires intentional efforts to develop meaningful connections among all sectors. These ideas have deep intellectual roots and can now draw on lessons from decades of on-the-ground experimentation.

The concept of a sustainable, local community food system emerged both from intellectual criticism of the agro-industrial food system and from community-based efforts to promote environmentally enhancing forms of economic development. Early roots can be traced to the 1960s and 1970s, when concerns began to be raised about the environmental damage caused by chemically intensive agriculture. While organic or sustainable production practices were viewed by many as necessary alternatives, by themselves these changes did not deal with a range of serious social and economic issues also associated with conventional food and agricultural practices. To address these, scholars and activists began to critique not only chemical regimes but also the effects of increasing scale, concentration of power, overreliance on specialized experts, and accounting systems, which allow large firms to internalize profits while externalizing costs to the larger community. These costs included serious problems, such as pollution, waste disposal, added burdens on welfare services, and deterioration of local tax bases. Driven by growth imperatives and by narrow economic conceptions of value and efficiency, conventional agriculture and food systems were viewed as sacrificing other values and priorities: healthy rural communities, a connection to

place, the pleasures and nutrition associated with good food, husbandry, good work, decent wages and working conditions, local economies, and appropriate technologies.

More recently, climate change concerns are providing a further rationale for local and regional food systems. These concerns include the environmental costs of shipping food long distances and the vulnerability of centralized production systems to climate shifts. For others, such as those in the food sovereignty movement, the primary driver of re-localization is the desire to maintain democratic control over the local food supply in the face of global commodification.

Increasingly, local and regional food and agricultural systems are being viewed as an important path toward creating a more sustainable future (Feenstra and Wilkins 2009). Beginning in the 1970s and continuing until today, scholar-practitioners from fields as diverse as economics (Schumacher 1973), agriculture (Berry 1977), nutrition (Gussow 1978), and sociology (Lyson 2004), along with many others, have articulated an alternative model for food and agricultural systems. At the core of many of these visions was an emphasis on building local connections between consumers and producers, between producers and communities, and between urban and rural areas. Many began to see the work of building relationships and connections as the path toward greater community control over their economic destiny. For others, the motivation was to reveal the human dimension underlying economic interactions, the beauty and the wisdom embodied in the natural world, and the possibilities of preserving what is unique within local and regional cultures, including the joy of sharing locally grown and lovingly prepared food.

Examples of Local Food System Strategies

Spurred by the intellectual critiques, and in some cases inspiring them, community-based projects to develop local and regional food systems began to emerge. Many local leaders are promoting local

food systems as an economic development strategy that supports local farmers, protects landscapes, and provides consumers with access to healthy and nutritious food. Local projects have taken many forms; just a few are highlighted here to suggest some of the most widely shared activities and emerging institutional connections.

Many of the most well-known and widespread local food system projects have involved developing new markets that more directly link farmers and consumers. These include farmers' markets whose numbers increased nationally from 1700 to more than 7800 between 1994 and 2012 (USDA Agricultural Marketing Service website n.d.), public food markets such as the Ferry Building in San Francisco or the Reading Terminal Market in Philadelphia, community-supported agriculture, and direct delivery options for institutions and retailers. Local leaders also created spaces for growing food such as community gardens or rooftop gardens, often in low-income neighborhoods where healthy food distribution was minimal.

In the late 1990s, nonprofits, school food service professionals, farmers, and community members realized that public schools could be another avenue through which to purchase and educate young people about local, sustainable foods (Feenstra and Ohmart 2012). The concept swept the nation as hundreds of schools and communities bought into the concept of healthier foods for their children and more economic security for regional farmers. According to the most recent statistics, more than 38,629 schools in all 50 states are involved in farm-to-school programs with more than \$354 million in sales to regional farmers estimated (National Farm to School Network website n.d.). The farm-to-school concept has now spread to other institutions such as colleges, universities, hospitals, prisons, and corporate cafeterias.

Noting that local governments have departments for necessities like housing and transportation, but none for food, many communities have begun to develop local or regional food policy councils. These councils are a means to institutionalize and better coordinate the newly emerging local food and agricultural activities and

programs (Clancy et al. 2007; Harper et al. 2009). A number of cities, counties, and even states now maintain food policy councils or alliances (Centers for Disease Control [CDC] 2010). The idea is that citizens want to participate more actively in controlling the policies governing their own food systems and help to plan for the future food security for their communities.

The private sector has played a major role also. Restaurants and cafés, inspired by Alice Waters' example at Chez Panisse in Berkeley, California, began searching for top quality, locally grown, sustainable ingredients from regional farmers. "Foragers," restaurant staff whose job it is to find local growers and ranchers, visit nearby farms and ranches and build personal relationships with the restaurant. The "Chefs Collaborative," a nonprofit network of chefs that are "changing the sustainable food landscape using the power of connections, education and responsible buying decisions" (Chefs Collaborative website n.d.), was formed in 1993 to support a growing group of restaurateurs committed to principles of environmental sustainability, seasonality, preserving diversity and traditional practices, and supporting local economies.

As one might expect with a movement that emphasizes locality, there is no single, overarching entity coordinating local food system efforts. However, in many states this work is supported by leading nonprofit organizations or university programs in the area of sustainable agriculture. In addition, local food activists have developed extensive national and international networks to share ideas and information. National professional associations such as Agriculture and Human Values, the Rural Sociological Society, the Community Development Society, the American Dietetic Association, and the American Planning Association now provide ongoing opportunities for discussing and analyzing local and regional food systems.

Internationally, the Slow Food Movement has emphasized building connections between the plate and the planet to counter the influence of fast food on society. The US affiliate, Slow Food USA, now has over 250,000 supporters, 25,000 members, and 225 chapters nationwide. The

organization advocates for food and farming policy that is good for the public, good for the planet, and good for farmers and workers (Slow Food USA website n.d.).

While funding for local and regional food systems remains miniscule in comparison to the resources agribusiness can call upon, the past two decades have witnessed a significant uptick in both public and private foundation support. For example, the USDA has supported these efforts through agencies such as the Agricultural Marketing Service (farmers' markets); the Cooperative State Research, Education, and Extension Service (regional research); the Sustainable Agriculture Research and Education Program (sustainable agriculture and food systems); and the National Institute for Food and Agriculture (research and outreach on sustainable food systems and food security). Foundations such as the W.K. Kellogg Foundation, the Robert Wood Johnson Foundation, the California Endowment, the Jesse Smith Noyes Foundation, and many others have supported the development of local food systems and encouraged communities to work toward making them self-sustaining.

Key Values and Principles in Developing Local and Regional Food Systems

As in other forms of community development work, staying on course requires grounding and deep commitment to underlying principles and values. Local food system leaders often cite their commitments to social, economic, and environmental justice and health, to democratic participation, to the importance of local wisdom and knowledge, to community spirit, and often to their own spiritual traditions. The challenge is holding true to these commitments to sustain work in tough times while remaining open to those who disagree or need pragmatic accommodations that may involve some compromise or trade-offs. Ultimately, this requires a form of public responsibility that can take many years to mature. While newcomers to communities can bring much to the table, there is no substitute for seasoned leadership with broad community

connections, a nuanced understanding of local realities, and practical judgment. At the same time, it is important to continually broaden the circle to include the full range of community voices, taking advantage of previously untapped or underappreciated leadership.

A review of local and regional food system projects in California found that community leaders had to work hard to create new social, political, and economic spaces and connections (Feenstra 2002). In identifying key elements of successful work, local leaders mentioned three themes most frequently: (1) public participation, (2) partnerships, and (3) policy work. At their best, these processes become ways in which core values and principles are embedded in everyday practice.

Public Participation

Local and regional food system projects often create new physical spaces where people can gather, such as farmers' markets or community gardens. But beyond and behind many of these visible spaces, they work by creating multiple opportunities for individuals to come together and talk about food system concerns, visions, and activities. Gradually, participants in these discussions develop mutual awareness and trust, which can be difficult to build given the pull of competing values and priorities. Working through friction or around obstacles is inherent in most projects, requiring patience, persistence, and skill in group processes and good communication. Some forms of public engagement are more immediately appealing, such as harvest fairs, school garden days, or other community events that create local celebrations. To stay engaged, the public must find the work not only meaningful but also fun and socially enriching. In all these ways, local food system leaders attempt to enact commitments to the value of democracy, sociability, and local culture.

Partnerships

Because food system work encompasses a wide range of goals, core groups frequently need to reach out to other individuals and organizations with complementary expertise or objectives. This

can include a broad range of community activists interested in sustainability or social justice, but also many mainstream institutions, including traditional agricultural organizations like the Farm Bureau or Cooperative Extension. Universities often are important partners, providing research, access to grants, technical skills, or facilitation. Universities can also provide a broader vision that helps locate local projects in a bigger picture, helping participant see their work as part of something larger. Partnership development is the way key values such as community are expressed, based on the importance given to expanding connections and relationships beyond typical boundaries.

Policy Work

For values to have lasting impact, they must become embedded in policy and institutions. Local and regional food system projects address policy issues at multiple levels – from school districts to city, county, state, or national governments. For example, some local areas have inserted food policy into their county's General Plan, and others have worked on farmland protection policies or school lunch policies. This work sometimes involves community-organizing efforts, such that youth or low-income workers or others are given an opportunity to voice their concerns in the democratic process. Many local areas find it important to articulate a compelling narrative that gives a rationale for emphasizing local food systems, while simultaneously working on better data to track the impact of initiatives.

Key Challenges Facing Local and Regional Food Systems

Working with a team of faculty and graduate students at UC Davis, a bibliography of peer-reviewed articles on local and regional food systems was recently compiled focusing on articles published since 2000 (UC SAREP website – community food system bibliography). The rapid growth of this literature (over 1600 articles were identified), mimicking the growth in community interest, is reflective of the surge in interest in this

field. But considerable challenges remain. An initial analysis of this literature, covering over 500 articles, identified three persistent strategic challenges facing community food system practitioners: (1) an economic challenge rooted in the difficulty of finding price points that work for farmers while ensuring low-income consumers have access to healthy food and food system workers have decent wages and benefits, (2) a social challenge to confront racial and class bias while forging practical solutions, and (3) a political challenge of reconciling “insider” and “outsider” strategies, the former emphasizing incremental reform and the latter systemic change (Campbell et al. 2013). These challenges resist simple solutions, posing difficult trade-offs between competing values.

Economic Challenge: Simultaneously Meeting the Needs of Farmers, Laborers, and Consumers

Research on local food systems brings into sharp relief the challenges and trade-offs involved in meeting the needs of different food system constituencies. The first challenge is finding a price point high enough to provide a stable and secure income for farmers but also low enough to ensure low-income consumers have access to healthy food. Even organizations that deeply believe in both these goals have a hard time achieving them simultaneously. By eliminating middlemen, farmer’s markets and other direct marketing schemes partially address this challenge. But research points to the need to supplement market-based solutions with public investments (Allen 2010; Campbell and Feenstra 2001).

A distinct but related lens on economic issues (and in turn race and class) involves labor, focusing on pay and working conditions for those who are employed to grow, harvest, process, market, distribute, and serve food. Since its inception, the sustainable agriculture movement has included activists motivated by concerns for farm workers. But it has also been critiqued by those who do not feel the movement is making enough progress in addressing farm or food system labor issues. Local food system initiatives face this same challenge but also the broader challenges of providing

sustainable wages and benefits for workers across the food system, such as those in food-processing industries.

Among the motivations for re-localization of food is the preservation of small- and medium-scale family farms. Yet this motive runs up against some evidence suggesting that there are better working conditions for farm labor on large farms than on smaller, organic farms (Shreck et al. 2006). The larger point is that all farmers – big and small, organic or conventional, locally oriented or global – participate in the same economic system and face strong pressures to reduce labor costs and protect profit margins.

Social Challenge: Confronting Racial and Class Bias

Another persistent challenge identified in the literature on local food systems concerns racial and class bias. At issue is the degree to which re-localization reinforces or exacerbates existing racial and class privileges, rather than challenges or transforms existing race/class relations. Some question whether initiatives led predominantly by white, well-to-do leaders can effectively address the social and cultural concerns and ideas of non-white and poor individuals and communities. At the same time, when food activists – mostly white and affluent – seek to expand healthy food options in low-income communities, they have been criticized for imposing their preference for minimally processed, local, and organic food on the rest of the population (Guthman 2011). Transcending these tensions will not be easy, but in many urban areas, social justice advocates have begun to demonstrate how people of color can take ownership of community food initiatives (Bonacich and Alimahomed-Wilson 2011).

Political Challenge: Reconciling Diverse Approaches to Creating Change

Local actors face additional trade-offs as they forge political strategies to create, implement, and support local food systems. For example, a common question is whether to pursue an “insider” or “outsider” strategy in making change, emphasizing reform at the margins or more fundamental systemic change (Campbell 2002).

Some advocates work within mainstream institutions in order to encourage incremental adoption of short-term objectives, compromising in the process and risking co-optation. Others seek deeper institutional change or work to build alternative systems that attempt to preserve movement values in their purest forms, even at the cost of short-term gains. Still others argue for middle ground solutions that weave together these approaches. Finding common ground amidst strategic differences can be challenging, but not impossible (Stevenson et al. 2007).

Another way the political challenge is framed in the literature has to do with the scale at which change strategies are focused. One approach emphasizes a bottom-up approach using local initiative and action to carve out alternatives in light of existing constraints and opportunities (Campbell and Feenstra 2001). A more top-down approach emphasizes political and economic reform on broader scales in order to create greater space in which local reform can advance. The skills and proclivities for working at these different scales are distinct, and while some local practitioners have succeeded in aligning themselves with larger coalitions, knitting the two together effectively can be elusive.

Summary

Local and regional food systems have emerged as one important strategy for restoring the vital connections between agriculture, food, environment, and health. They have emerged from local efforts to regain control over the relationship to the food and agricultural system and as a response to the costs to communities of the agri-industrial model of food and agriculture. The projects emphasize public participation, partnerships, policy work, and the principles and values associated with sustainability, equity, and democracy. In pursuing these values and goals, local food system projects must navigate persistent strategic challenges which often require difficult trade-offs among values. These include finding strategies that simultaneously benefit farmers and low-income consumers, dealing with race and class issues

given the predominant white and well-to-do constituency in many local projects, and striking the right political balance between incremental reform at the local level and pursuit of broader systemic changes. A growing body of research is tracking the work and more intentional partnerships between academics and practitioners are needed to capitalize on local experience to generate usable knowledge.

100-mile diet; Local eating; Local food sourcing; Locavore; Locavore diet; Locavore lifestyle; Locavore philosophy

Introduction

The term “locavore” was coined in 2005 by Jessica Prentice, who, along with Sage Van Wing and Dede Sampson, made a commitment to eat only food sourced within a 100-mile radius of their homes in Northern California. This effort

was publicized in the media during World Environment Day in San Francisco and subsequently entered the lexicon. While this might have been the first documented use of the term “locavore,” the idea – and necessity – of eating a local diet was not a new one.

The seeds of the locavore movement may have been planted over a long period of time, but it was not until the first decade of the twenty-first century that people became very focused on the localized provenance of their food, due to increased interest in environmental ethics, health, and economic concerns and a movement away from corporate farms and industrialization in foods. When this movement was given a name and parameters in 2005, it grew steadily as a lifestyle – embraced wholeheartedly by some who sought to only source their food locally – but also grew as a lifestyle choice of those who shifted more of their food procurement to local sources. Proponents claimed that local sourcing kept money in the local economy, supported community, and promoted personal and environmental health through the conscious and sustainable business practices of the farmers and other food businesses that locavores supported. However, critics were quick to point to new studies that indicated that local food procurement was not the only or best way to ensure sound environmental practices, that a localized food system could denigrate food security in both America and around the world, and that accepting and working with a more globalized food system could do better at addressing the initial concerns of early locavores.

While the locavore movement as it was conceived in 2005 is still in its infancy, many of those who consider themselves locavores look at local food choices as more of a philosophy to source from smaller, environmentally conscious farms, who adhere to similar values as themselves.

History

Before industrialization and advances in refrigeration, mass production, food preservation, and transportation, food was traditionally sourced locally. The first permanent European settlers in

northeastern North America brought with them some provisions. However, soon an agricultural community model was established, and early settlers fed themselves from personal farms or items that were traded or sold within growing villages and cities. By the 1600s the settlers had access to certain exotics such as tea, sugar, and coffee as standard fare in their diets due to their early availability via global trade routes, and by the 1700s a number of nonlocal products were fully integrated with the otherwise mostly locally sourced diet.

By the 1800s, large urban areas were growing in the north, creating low-income slums with little access to fresh produce. Farm animals, such as dairy cows, were still being kept within city limits, but the conditions were increasingly unsanitary leading to spoilage and illness. Outside of prime harvest times, hearty vegetables like cabbage and foods preserved in salt or vinegar provided the main sustenance for urban dwellers. Beyond urban centers, small towns and cities were established as the hub for a mainly agricultural society. A wide variety of pickling and preservation methods were used to keep local produce edible for months past harvest, which were developed by early settlers or brought over mainly from Europe. However, those who could afford it expanded their diet with foods imported from other parts of the country and from around the world.

There was continual migration from Europe, forcibly from Africa, and by 1820 the start of a wave from Asia – all which increased exponentially in the ensuing decades with the advent of steamships. With the greater number of people from many nationalities arriving, food and cultural migration and influences began in earnest, as did the introduction of many new flavors, ingredients, dishes, and preservation techniques – expanding what was grown locally and also increasing the demand for nonlocal goods.

Technological advances greatly affected foodways by the mid-1800s as well. The invention of the cast-iron stove meant that open fires were no longer required to cook, and the increasing availability of refrigeration – both via transportation methods and at home – meant that fresh foods could travel far from their place of origin and

stay edible longer, setting the stage for perishables to be sourced from farther away and making local food less important to the average American's diet. Industries were soon being built around large-scale canning, which began to centralize the farming of certain produce and further lower people's reliance upon locally grown food. Also, this marked a shift from taste and flavor being the primary area where food was judged to safety and uniformity becoming more important (Roudot 2004). The late 1800s brought even cheaper sugar to North America, and the invention of "milk chocolate" – or candy made with cocoa powder from Central America and soon farther afield – led to even greater popularity of this nonlocal exotic and expanded the global nature of the average American's perception of food culture.

Further technological advances in food preservation, refrigeration, and sanitation spurred cultural changes, and women in both urban and rural areas were more likely to purchase staples like pickles, cheese, and canned goods at a store rather than make them at home. Fewer homes had personal gardens as well, and in 1920, the urban population of the country exceeded the rural population for the first time, marking the tipping point for the movement toward industrialized food and away from subsistence farming and local food sourcing (Swanson 2012).

The two world wars also greatly influenced the movement away from locally sourced products and toward convenience foods. With more women in the workforce, less time was spent on food preparation. Packaged foods like TV dinners became popular, and the introduction of fast-food chains made eating out more accessible. Agriculture moved toward monoculture as well, all of which helped push culinary trends toward flavor homogenization, and after the rationing of the Second World War, feeding people food of uniform quality and safety became the highest priority, rather than flavor (Roudot 2004). Common household activities from a generation prior, such as canning, pickling, and cheese-making, were becoming increasingly rare in urban and suburban homes, and the supermarket offerings of these products were mass-produced.

The "counterculture" movement of the 1960s reinvigorated some interest in gardening, vegetarianism, and food co-ops and brought attention to the potential health risks of the red meat- and preservative-heavy meals that had become prevalent in American homes, while Rachel Carson's 1962 book *Silent Spring* highlighted the environmental consequences of the rampant pesticide usage of large-scale farms and, by extension, industrial farming practices. Also important was the 1973 film *Soylent Green* which presented a dystopian future where all foods were processed and the environment was ravaged, causing death, disease, and war among humans. These factors influenced a shift in culinary tastes that gained speed in the 1970s when Alice Waters began to popularize "Californian" cuisine that emphasized fresh, seasonal ingredients and traditional preparation methods. The growing movement began to evolve into a resurgence in interest in specialty cheeses, gardening, and small-farm production, further spurred by Wendell Berry's 1974 World's Fair speech and subsequent publications against industrial farming, which helped carry the "back-to-the-land" movement into the 1980s (Paxon 2010). Berry continues to be an inspiration to those interested in local food sourcing and still frequently speaks about his perceived ills of capitalism and the industrialization of the food system.

By the 1980s, the number of small and "organic" farms, long in decline, was starting to increase, and the first federal laws standardizing organic practices were passed in 1990. Consumer demand for organic food grew steadily, in part because of the desire to be more environmentally responsible and also more conscious about what chemicals one was exposed to. However, as the organic food industry expanded, some of the negative characteristics of industrialized conventional food remained. Organic foods were being grown and shipped from around the world, where regulation was lax or faulty and large conventional food producers were using technically organic practices while perpetuating some of the same business models that turned consumers away from industrialized conventional farming in the first place, such as crop monoculture and

ultrapasteurization of dairy. The locavore movement grew out of the disillusionment of those who supported the organic movement but wanted more transparency and control over their food sources. Many who sought organic food for ideological reasons wanted to support growers of produce and livestock in ways that were more aligned with their values.

This cultural shift was apparent in a small but active portion of the population into the new millennium. As the first rumblings of the recession were being felt early in the 2000s, so rose the interest in family gardens, in small-scale farming, and in skills like preserving and cheese-making – and by 2005 the term “locavore” was coined. Culinary culture also saw the birth and popularization of the international “Slow Food” movement – akin to Alice Waters’s Californian cuisine and founded by the Italian Carlo Petrini – that called for a return to locally grown, seasonal, traditional, and sustainable food sourcing and preparation.

This relatively small but significant shift in food trends in the mid-2000s occurred in part because it became increasingly easier to source local food. Since the US Department of Agriculture (USDA) began publishing the national directory of farmer’s markets in 1994, the number of farmer’s markets had more than quadrupled nationally by 2012 (USDA 2012). With these new markets came new customers interested in fresh, high-quality, local produce and products made from ingredients – and by people – they felt they could trust. In addition, these markets provided a literal marketplace where small and start-up businesses could sell products made from local ingredients and begin to gain customers relatively easily, with no need for distributors or middlemen. Add to this the recession that began in 2007 and an increase in unemployment and underemployment. This spurred people looking to cut costs to grow their own food, resulting in a spike of sales of seeds in 2007 and 43 million American households growing their own food by 2009 (Sanburn 2011). An additional effect of this was the increased understanding of the seasonality of produce and the experience of the improved taste of fresh, garden-grown goods.

This also led to the continued growth of people starting food-based businesses (Casserly 2012); a greater cultural interest in homemade, local, and high-quality food products; and more people trying traditional preserving and pickling methods to continue to eat locally sourced food out of season, thereby reducing the need for imported produce.

Barbara Kingsolver’s 2007 nonfiction book *Animal Vegetable Miracle*, which detailed a year in the life of her family in Southern Appalachia growing or otherwise locally sourcing nearly all of their food, also did much to publicize the new locavore movement during this period. This served as an inspiration for others to make efforts to do the same and spawned numerous locavore experiments, blogs, and articles. At the same time, more investigative works such as 2008’s *In Defense of Food* by Michael Pollan took a hard look at the realities of North America’s food system and its negative implications on the population’s health and the environment, inspiring people to source their meat and produce from local farmers who offered more transparency in their methods of production.

These popular books, coupled with the recession and the exponential growth of farmer’s markets, inspired more people to embrace the idea of “locavorism” – resulting in “locavore” being named the “Word of the Year” by the Oxford American Dictionary in 2007. While this is an emerging field, there have been a number of studies done in the past decade that look at the claims of a local diet and the perceived ills of the conventional food system. The arguments presented for locavorism were numerous and included lowering environmental impact in transporting and refrigerating goods to local communities, rather than farther afield; lessening the use of chemicals, as many of these farmers practiced organic or otherwise low- or no-chemical methods of planting, harvesting, fertilization, and pest prevention; and keeping money in the local economy by supporting small farmers. Those who supported a more global approach to food sourcing countered the above arguments with alternate research and noted the increasing world population and need to address food security and the

ingrained presence of certain exotic foods in the Western culture as a major defense of a globally sourced diet.

Environmental Impact

The increase in interest for locally sourced food has inevitably sparked debate about the true benefits of eating a local diet. One of the primary arguments for a local diet was a desire for food that did not need to be shipped far, thus limiting fossil fuels used to transport goods all over the country or world, and to keep it cool during that journey. A study in 2005 demonstrated how far a typical meal might travel to get to one's plate: Rich Pirog, the associate director of the Leopold Center for Sustainable Agriculture at Iowa State University, showed how the ingredients that go into a cup of strawberry yogurt traveled 2211 miles just to reach the processing plant – not including how far it travels to get to the consumer's fridge or the fossil fuels used to keep it cool on this journey. This study, and others like it, sparked supporters of local food who noted that it was relatively easy to agree that yogurt made from local milk, sweetened with local fruit and honey, would have a smaller "carbon footprint," defined as a total set of greenhouse gas emissions caused by the production of a product. However, using the carbon footprint calculation as the main reason to buy locally sourced food brought up counterarguments and questions about the feasibility of this calculation for every food consumed. Detractors noted that shipping by rail is known to be ten times more efficient than by truck, which can alter the carbon footprint of a product depending on its transportation method and not its place of provenance, while others noted that the overall environmental cost of food transportation was negligible compared to other environmental concerns (McWilliams 2009). However, Pirog along with a group of researchers also conducted a study that analyzed the average distance traveled of a variety of produce items to Iowa markets, looking at local, regional, and conventional transportation methods. They found that conventional methods took food on a 1500-mile ride – versus less than

fifty for locally sourced items – and emitted 4–17 times more carbon dioxide. A comparable study in Canada found that replacing imported food with similar local products would be a benefit to the environment equivalent to taking more than 16,000 cars off the road (DeWeertd 2011). However, this debate brought up important alternatives for lowering the carbon footprint of food sourcing without insisting upon only eating foods sourced within a specific radius, thereby causing some strict proponents of locavorism to rethink their reliance on carbon footprint calculation as the sole basis for their dietary choices.

Economic Issues

Those who support a focus on local eating have also begun emphasizing its economic and community-building aspects noting that buying local keeps more money in the local economy. The movement for local eating has evolved to a larger "buy local" philosophy, with many studies asserting the economic benefit of supporting smaller, local farms and food-related businesses. One example notes that 68% of money spent at a locally owned business stays within the immediate economy, while only 43% of money spent at a chain store remains local (Frazier 2007). Thus, many locavores argue that with food costs making up 10–20% of the average American's budget, keeping that money within the local community helps spur the economy while also helping environmental and personal health.

A recent USDA study also states that expanding local food systems increases employment and income in a community and can, but does not necessarily, reduce greenhouse gas emission (Martines et al. 2010). Although, the same study also noted insufficient evidence to support whether local food access improves diet or food security.

However, it is exactly that notion of food security and cost that critics of locavorism cite when they declare this lifestyle both unsustainable on a global scale and elitist. Many local food proponents admit that locally sourced food often costs more than its industrial counterpart and acknowledge that barriers such as access to

farmer's markets and other retail operations offering local produce can also limit access to consumers of lower socioeconomic status. Their counterargument is to fight the governmental system that overwhelmingly supports corporate food systems through subsidies, regulations, and other federal programs while making it easier to produce, distribute, and sell local, organic produce to a wider consumer base.

There has been a growing middle ground between ardent locavores and local food critics, most apparent with the increasing number of food co-ops around the country. Supporters of food co-ops, or groups who cooperatively buy food – often focusing upon organic, local, and sustainably sourced items – are attempting to address the issues of food insecurity and claims of elitism. The co-ops are often member owned or run and offer prices at a distinct discount from traditional grocery stores through methods such as bulk and seasonal purchases.

Proponents of locavorism cite these co-ops, weekly farmer's markets, cheese-making classes, and other community activities as having capital beyond monetary or environmental. The social benefits of the growing consciousness about local food sourcing are often cited as a positive effect beyond environmental or economic, by making a place for social activity and promoting a sense of community (Brown and Miller 2008). Additionally, proponents note that creating community through local food sourcing also has the potential to help shift broader support to change the systems in place that make conventional and mass-produced foods cheaper, organic, and sustainable and foods from smaller farms more expensive. These social benefits also often extend to help mitigate the sometimes increased price of locally sourced food by creating systems where, for example, more affluent community members help subsidize CSA subscriptions for lower-income members.

Feasibility for Larger Implementation

Another argument against strictly local eating is the feasibility of this as an option to feed the

world's growing population. The 2012 book *Locavore's Dilemma: In Praise of the 10,000-Mile Diet* argued that our industrialized and globally sourcing food system actually created many positive changes in food policy – such as stronger safety measures and greater food security – and that a strictly local diet would increase food costs, poverty, and food insecurity (Desrochers and Hiroko 2012).

James E. McWilliams also makes a similar argument in his 2009 book *Just Food: Where Locavores Get It Wrong and How We Can Truly Eat Responsibly*. He notes that using food miles as the main delineator for a sustainable diet does little to solve the larger environmental, health, and economic issues that locavores and concerned consumers alike cite as important to consider in sourcing food. His research asserts that with the world's population projected to reach 9.5 billion people by 2050, there needs to be realistic and environmentally sustainable methods of feeding this vast number. However, McWilliams and others who believe that there are ways to improve our current food system without advocating for a strictly localized one argue that the answer to this dire global problem lies in part in using a combination of approaches including technological advances, like responsible genetically modified crops that can help crops be more productive and disease-resistant; moving toward large-scale agriculture that is more environmentally healthy; and exploring new avenues for nutrition, such as aquaculture. These more holistic approaches toward global food sustainability can embrace many of the same values that a locavore prizes – food that is kinder to the environment, produced using transparent methods, and financially supports all members of food production and not primarily executives of large corporations – but does so in a manner that is realistic about the needs of the growing world population and the existing global nature of food production.

Locavores counter the argument that locally sourced food cannot feed the world's population, however, with statistics that note that global food systems already produce enough nutrition to feed 12 billion people, and that the issue lies not in greater production, but rather helping food get to

those who are in need. They assert that a localized system with more smaller farms closer to large population centers can help address malnutrition (Philpott 2012). Further, local sourcing proponents posit that keeping arable land in the hands of local farmers and away from large corporations can only help food security and economic stability.

Food Culture

Even model locavores such as Barbara Kingsolver allowed a few specific exotic foods in her family's otherwise locally sourced diet, reflecting the ingrained nature of certain nonlocal ingredients in the Western food culture. For centuries foods such as sugar, coffee, chocolate, spices, and tea have been imported from around the world and have become a vital part of many Westerner's daily food rituals. Almost all ardent locavores who have written about and publicized their food sourcing methods in an effort to support this lifestyle and its values have made exceptions for one or more products. These exceptions often are made with caveats for fair-trade procurement – defined as a trading partnership, often certified by an outside nonprofit governing agency, that ensures that the rights of marginalized producers and workers are paid fairly and that the goods themselves are produced in an environmentally and economically sustainable manner. Locavores who support fair-trade exotic products argue that items like coffee or chocolate are a desired and necessary part of their diet and, by only buying certified fair-trade items, they can ensure that the values they ascribe to the rest of their locally sourced diet are present in the procurement of a few exotic items as well.

Critics of a strictly locavore diet, however, would be quick to point out the hypocrisy of these exceptions, noting that once any nonlocal product is deemed an allowable item, it dilutes the strict locavore's stated philosophy. Further, these critics cite the global nature of food culture in general and assert that greater global understanding is found through exploring other culture through edibles.

Summary

While there is no one definition of locavorism, most accept this lifestyle to be defined as one that only sources food from within a specified radius of 100–500 miles and generally ascribes to organic and environmentally conscious farming practices. Those in favor of a local diet cite many positive attributes, such as a food system that is kinder to the environment and keeps money in the local economy, and consider locavorism more of a holistic philosophy of consuming products from smaller, more environmentally conscious purveyors. Critics note the increased cost and potential food insecurity that can result from a focus on only locally sourced goods, as well as the ingrained nature of exotics in the Western diet. However, most supporters and even some critics of a strict locavore diet do admit that there are many positive aspects to sourcing more food from smaller, often local, farms and other purveyors whose philosophy about environmental and economic issues are more consumer focused. Thus, while a locavore is focused on distance-based food sourcing, the increased interest and studies surrounding this lifestyle have expanded its definition to include a broader set of values rather than a rigid lifestyle to which one strictly adheres.

Ethical principles; Food choice; Food marketing;
Utility theory

Introduction

This entry explores the interface between food ethics, food marketing, and food policy, in the context of diet and health. It confronts two ethical issues which arise within this subject: whether food marketing can be held responsible for poor diets; and the extent to which it is legitimate for food policies to restrict consumer food choice on grounds of diet and health. The essay considers how, respectively, ethical principles and economic theory can help.

Ethical Principles and Economic Theory

Ben Mepham (2008) has articulated three principles as a guide to ethical decisions. These are the following:

- **Respect for Well-Being**

This is derived from the utilitarian theory of the British nineteenth-century political economists Jeremy Bentham and John Stuart Mill and epitomized by the famous quotation “The greatest good for the greatest number.”

- **Respect for Autonomy (Freedom and Choice)**

This is associated with the deontological theory developed by eighteenth-century philosopher Immanuel Kant and concerns the rights and duties we have as individuals with respect to other individuals – “Do unto others what you would have done to yourself.”

- **Respect for Justice (Fairness)**

Originated by the contemporary American philosopher, John Rawls, and based on the concept of an egalitarian society with equal rights and opportunities.

Economic theory has developed the utilitarian principle into a utility theory of consumption, in which it is assumed that consumers take product purchase decisions, constrained by budgets, designed to maximize the utility (satisfaction) they derived from consumption. The relationship between different patterns of product choice and utility is known as the consumer’s “utility function.” For a consumer to be able to maximize his utility in this sense, the principle of autonomy needs to apply – he needs “freedom to choose” – and issues around consumer food choice are central to the debate over diet and health.

Food Marketing

First, distinguish between the use of the word “marketing” to describe a subject of study, and as a description of the activity of a company “communicating” with its customers (Ritson 1997a). There are many definitions for the former, but most would embrace reference to “accurately identifying and meeting customer [in our case, food consumers] needs and wants”; and superficially at least there is nothing unethical about that. It is the second use of the word that has brought “marketing” a bad press, where the term is often regarded as synonymous with advertising and other methods of product promotion. Defenders of marketing in this sense would argue that marketing communication simply allows food consumers to make informed choices to meet their needs and wants – a sort of win-win situation in which food consumers are able, in terms of economics, to maximize their well-being and food suppliers their profitability. Under this interpretation, marketing becomes consistent with the argument of Adam Smith (1776) that “in pursuing his own advantage” every individual was “led by an invisible hand to promote an end which was not

part of his intention” namely to “render the annual revenue of society as great as it could be.”

The counterargument on the merits of marketing is summarized by Tim Jackson (2009) as:

... people are being persuaded to spend money we don't have, on things we don't need, to create impression that won't last, on people we don't care about.

As far as having a negative effect on food consumers, this can be narrowed down to two main concerns. The first is marketing communication which includes messages which mislead consumers over health aspects of a food product. This can vary, at one extreme, from what one could describe as merely subtle use of words (e.g., “90% fat free”) to, at the other, bold and unsubstantiated health claims. “Informing the consumer” becomes “misinforming the consumer.”

Second is where “informing” merges into “persuasion.” The dictionary definition of “persuade” is “to cause a person to believe or do something by reasoning with him.” In this case “do something” is consume more (or perhaps sometimes less) of a particular food, and “reasoning” is marketing communication. Marketing is no longer simply identifying consumer “needs and wants,” but creating them. There are two reasons why this might have a negative impact on consumers. First, as the effect is to increase the range of consumer needs and wants, then people with limited income are more likely to be dissatisfied over the pattern of consumption they actually achieve. Second, and more fundamentally, is if consumers are “persuaded” to develop less healthy diets.

Take the current interest in “sugary drinks” as an example. Sponsorship of sporting events can be argued as misleading by linking the product with a healthy lifestyle; and much of advertising and promotion can be regarded as attempting to persuade people to consume more of the product. One only has to invoke the principle of well-being to be able to judge marketing communication as “unethical” in these circumstances. Similarly, within economic theory, the consumer’s utility function is being manipulated, and the decisions he takes can no longer be regarded as maximizing his utility (satisfaction) for a given income.

Socially Responsible Marketing

Returning however to the textbook definition, with marketing regarded as genuinely merely identifying and meeting consumer needs and wants, not creating them, then things become more complicated. What if consumers do want (if not need!) sugary drinks and are fully aware of the dietary implications? At this point the debate switches from the negative of “unethical” to the positive of what is “ethical marketing” relative to diet and health. A school of thought has developed that argues that responsible food businesses have a duty to restrict access for consumers to “unhealthy” foods, and this practice has become known as “choice editing.” This in turn raises the question of whether a conflict now arises between the ethical principles of well-being and autonomy, and phrases such as “consumer sovereignty” and “freedom of choice” appear. Defenders of choice editing would argue:

- It is an illusion to imply that consumers have unlimited choice. Decisions are taken throughout the supply chain which restrict the choice of food products available to consumers. In these circumstances, the health and well-being of consumers should become paramount in determining the food basket from which people can “freely choose.”
- Consumers are faced with a bewildering array of thousands of products on the supermarket shelves. Even the socially responsible, well-informed, health-aware consumer will find it almost impossible to achieve the mix of products that they would choose with perfect information and unlimited time. Choice editing will therefore help them to move toward optimum decisions or, in terms of economic theory, to maximize their utility.
- Most people are not well informed about the relationship between their diets and their health. Choice editing is one way of forcing them to take the consumption decisions which they would if better informed.
- The issue is complicated because the term choice editing is used perhaps more often to refer to aspects of production rather than

consumption by, for example, restricting access to products from non-sustainable sources or only stocking “fair trade” products. However, consumer research suggests that many people would quite like the food industry to assume the function of ensuring that they are “responsible” food consumers. This particularly relates to sustainability and production methods, but may extend to healthy diets.

The head of marketing and procurement for Sodexo UK, a large food service company, comments (Hanson 2012):

We develop recipes... to embed the principles of a healthy and balanced diet into all our dishes. This includes removing trans fats, reducing levels of salt, fat and sugar, and increasing fruit and vegetable content...

Ultimately, choice editing is not about imposing... A critical mass of committed food buyers and producers, who are able and prepared to make choices on behalf of consumers... will help to convert favourite foodie cravings into commitments and actions that support a more sustainable future.

Encouraging as this is, it is arguable that choice editing can only nibble at the margins of the problem of diet and health. Many food firms will not adopt it; and large areas of food consumption will be unaffected. This leads to the view that Governments should step in.

Policy Intervention

Although in principle choice editing could be accused of being in conflict with consumer autonomy, for the reasons listed above, “responsible” food marketing of this kind appears to attract almost universal public and political support. In contrast, Government policies which attempt to restrict consumer food choice are sometimes subject to sustained hostility.

Public policies which merely “encourage” consumers to adopt healthy diets – such as the British 5-a-day fruit and vegetable campaign – are usually welcomed. Even here, though, not everyone agrees. The British Minister of Education is

reported (Mail Online 2012a, b) as describing the British Food Standards Agency as having gone from:

a body that was responsible for governing the safety of food to one that became yet another meddling and nanny organisation that was telling us what we should eat and in what proportion.

There are of course more explicit ways for a policy to limit consumer food choice. A recent example was the announcement by New York Mayor Michael Bloomberg that he planned to prohibit the sale of sugary drinks in containers above a certain size, in restaurants, movie theaters, and street carts. The Center for Consumer Freedom echoed that of the British Minister of Education, with an advertisement in the New York Times depicting the Mayor as a Nanny under the caption:

New Yorkers need a Mayor, not a Nanny... What next? Limits on the width of a pizza slice, size of a hamburger or amount of cream cheese on your bagel.

The American Beverage Association called the plan “ridiculously unreasonable, unsound, and incongruous” (Mail Online 2012a, b) and subsequently sued the City, challenging the ban.

On the eve of the implementation of the policy, a State Supreme Court judge ruled the ban as invalid, describing it as “arbitrary and capricious” (CNBC 2013).

“Arbitrary and capricious” is not too far from “unethical.” Can ethical principles and economic theory therefore help in deciding whether there are limits to the legitimacy of food policy methods which seek to improve diets?

First, policies to combat marketing techniques which include false or misleading messages over the health and nutritional properties of a food product are generally regarded as legitimate. Legislation on this in the European Union (Davies 2013) has recently become much more stringent, with health claims requiring prior approval from the European Food Safety Authority (EFSA) on the basis of scientific evidence submitted by the food manufacturer. (Previously, in the UK, it was up to local Food Standards Officers to challenge the wording of claims on foods already on the

market.) Although consumer groups have welcomed this development, some food businesses regard the degree of evidence required by EFSA as too high. They argue that “qualified health claims” should be allowed. Claims are rejected if they rely simply on “good evidence of a relationship” or “the balance of evidence,” whereas food firms argue that the interests of consumers would be better served if the manufacturer was allowed to inform consumers of potential health benefits even when there was less certainty over the validity of the claim. In the USA, conditional claims that clearly state the level of uncertainty and the nature of the research behind the claim are permitted (Food Ethics Council 2009).

Second, there is an important contribution of economics to the debate – the concept of social costs (or benefits), sometimes known as “externalities.” Poor diet has an adverse impact on the well-being of everyone, via the increased national costs of health care, not just the well-being of the obese, and policies to improve diets are often justified on these grounds, probably because of a reluctance to become involved in the debate over consumer choice. Economists have developed techniques for attempting to value the social cost of poor diets; it then becomes a matter of judgment within ethics as to whether the positive benefit under the principle of well-being overrides the impact on consumer autonomy under the application of ethical principles.

Third, as already mentioned in the context of choice editing, the case for altering patterns of food consumption in the interests food consumers themselves is influenced by consumer awareness. The economic theory of utility would regard it as legitimate to attempt to alter diets if there was evidence that consumers were misinformed about the consequences to themselves of their consumption decisions. The problem arises when the concept of the “acceptability” of risks is explored. With respect to food consumption, people regard some food safety risks as “more acceptable” than others.

This problem is particularly prevalent when considering the health risks of food consumer autonomy. There appears to be an inverse relationship between the food safety risks which

concern consumers and the aspects of food safety which scientific evidence implies should concern consumers. To illustrate this, the first Chairman of the British Food Standards Agency, John Krebs, provided estimates of deaths per year in the UK related to diet and food, listed in Table 1.

Contrast that with the outcome of a consumer survey (Table 2) which asked “Which of these concern you about food safety?”

This of course does not resolve the question of the extent to which “lack of concern” reflects poor understanding of food-related health risks, but there is now a substantial body of evidence (e.g., Miles et al. 2003; Ritson and Kuznesof 2006) that people find risks perceived of as technologically driven and uncontrollable as “less acceptable” than those perceived as “more natural” and subject to personal control.

Marketing, Food Policy, Diet, and Health, Table 1 Estimate of annual UK deaths related to food and diet

Risk	Number of deaths
Cardiovascular disease	73,000
Cancer	34,000
Food-borne illnesses	50
Food allergy	20
vCJD	15
Genetic modification, pesticides, growth hormones	0

Marketing, Food Policy, Diet, and Health, Table 2 Proportion of consumers expressing concern over food risks

Risk	Proportion expressing concern (%)
Risk of chronic disease due to poor diet	25
Food poisoning	48
BSE “mad cow disease/CJD”	52
New food technology (e.g., genetic modification)	60
Chemicals in food (e.g., pesticide residues)	78

Source: Tables prepared from data cited in Ritson and Kuznesof (2006)

Thus, the application of ethical principles and economic theory justifies food policies aimed at altering patterns of food consumption on the grounds of the social cost of diet induced poor health; and also where there is evidence that consumers are not fully aware of the health implications of their diets, or are being misled by marketing messages, and would take different purchase decisions if better informed. However, the fact that consumers regard some food-related health risks as “more acceptable” than others raises a difficult ethical issue. The economic theory of utility assumes that the well-informed consumer is the best judge of his own utility.

Food Policy Mechanisms

Finally, are some methods of altering patterns of food consumption “more ethical” than others? Here there is a useful distinction that economists make which may help, at least to clarify thinking on the subject. The distinction is between methods which alter utility functions (crudely, what people want to do) and methods which alter what people consume, without altering their utility functions.

Methods which alter utility functions are, primarily, “education” and “social marketing.” Education – making people better informed about the impact of their consumption decisions – is fine and passes the economics test above. With social marketing – the application of marketing techniques to achieve public interest objectives – we return to the issue of whether it “informs” or “persuades.” Is it ethical to persuade consumers to eat more healthily, even if their change in diet is for reasons other than knowing it is more healthy, if it is “unethical” for food firms to persuade people to choose unhealthy diets? In other words, it is perhaps not the marketing technique which is unethical, but the motive behind it. (The end justifies the means.)

There are a variety of ways in which a policy can alter diets without altering utility functions. The most prominent are price manipulation and restricted availability. In principle, a price policy aimed at improving diets could operate either by taxing unhealthy foods or by subsidizing healthy

ones. The former is sometimes called a “fat tax,” which can conveniently refer either to the food being taxed or the problem being addressed by the policy. To many people, subsidizing healthy foods is much more acceptable – it is seen as not impacting on consumer choice. Yet taxpayers lose with subsidies and gain with taxes, and economists would argue that it is legitimate to raise the price of those food products which contribute to the social cost of health care caused by bad diets (externalities). This money could be used to finance health campaigns or to subsidize fruit and vegetables. A recent report from Sustain (2013) advocates a tax on sugary drinks primarily on the grounds that the money raised could be used to fund health awareness programs.

There is another reason why taxing unhealthy foods can be defended; other Government policies can have a substantial impact upon the level and balance of food prices. For example, for many years the Common Agricultural Policy (CAP) of the European Union, as a consequence of its measures aimed at supporting prices received by farmers, is estimated to have increased food prices in the UK on average by the equivalent of a 15% tax (Ritson 1997b). More fundamentally, however, the price raising effect of the policy varied from product to product, pushing up most the consumer prices of dairy products and sugar – equivalent to a tax of 100% or more, with little or no price raising effect on fruit and vegetables. Quite by accident, the CAP was a kind of “fat tax,” pitched at a level well in excess of any now suggested as a way of improving diets. It seems difficult to argue that it is ethical to push up food prices for low-income consumers in order to aid farming, but not to improve the well-being of consumers themselves.

Summary

- “Choice editing,” with the objective of improving consumer diets, can be justified as “ethical marketing.”
- Policy intervention is legitimate when it is used to combat misleading (or “unethical”) marketing with respect to health claims, though questions have been raised over the degree of

evidence required before it is in the interest of consumers to inform them of a potential health benefit.

- The benefit to society as a whole of better diets, because of the externalities associated with the health consequences of poor diets, will normally allow the principle of well-being to override that of autonomy as a justification for policy intervention.
- Food policy intervention is justified where there is evidence that consumers are unaware of the degree to which there is a link between their diets and their health. This need not necessarily be restricted to policies which attempt to “educate” the public to take more informed decisions, but could include policies which simply have the effect of altering patterns of food consumption.
- The fact that consumers find some food-related health risks “more acceptable” than others raises a difficult ethical issue – to what extent has society a responsibility for “forcing” consumers to alter their diets in a way that society believes to be in their own interests?
- Finally, this entry leaves the reader with two further questions. Is there an ethical distinction between subsidizing good food and taxing bad food? And is there a distinction in food ethics between altering what people want to do – even if this involves “persuading them” – and altering what they do, without altering what they want to do?

Introduction

Breadth of Work

Max Weber (1863–1920) was a classical sociologist who wrote about agriculture, politics, economics, bureaucracy, social stratification, capitalism, and many other subjects. He is well known for his insistence that ideas and belief systems create society and technology, and not the other way around. For example, he claimed that an ideology of “a spirit” underlies modern capitalism and used agriculture to illustrate this

point. Other agricultural issues that he addressed from a sociological viewpoint included agrarian policy in the ancient civilizations, and German agrarian policy during the period between about 1890 and about 1910.

Weber is best known for his understanding of capitalism, which in many respects starts with his understanding of peasants and their relationship to the land. Weber said that beliefs about the nature of labor and work, rather than the technology, made modern capitalism possible in the first place. For capitalism to work, he said, people must believe that it is important to make ever more money, which can be invested to make yet more money. For this to happen though, people need to believe that making ever more money in the marketplace is more important than having leisure time, and more important than loyalty to family and clan. What must become most important is becoming rich for its own sake. He called this “the capitalist ethic.” For this reason, Weber wrote, modern society has populations dedicated to a work ethic, while earlier feudal societies were dedicated to an ethic of “personal loyalty.”

At the root of many of Weber’s essays was an understanding that “the soil” is the basis of human civilization (Radkau 2009, p. 72). Weber’s agricultural examples were used in his early writings about agriculture in ancient Rome, his mid-career masterpiece *The Protestant Ethic and the Spirit of Capitalism* (1904–1905/1998), and finally in his writings about the shift from subsistence peasant agriculture to modern capitalist agriculture in eastern Germany during the early twentieth century (see, e.g., Weber 1906/1947). Weber was always asking, what do people think about the nature of work, land, and economy? How does this affect the way society is ordered, including how the agricultural system is organized? In each case, Weber insists, there will be a dominant ideology that drives work and agricultural production. This affects how land, labor, and production are viewed, traded, taxed, bought, and sold.

Feudal Versus Modern Agriculture

On the feudal manors which were still found in eastern Germany while Weber was writing

between 1890 and 1910, there was a belief that the patrimonial lord has a fatherlike relationship to “his” peasantry – that is, the lord and peasants shared mutual but unequal responsibilities to each other that were like a father and child. The “father” was to protect the peasants whether or not they made a profit, while the peasants were to obey the “father.” Such relationships were validated in the deeply religious character of this society. Notably the feudal manor was a mostly self-contained unit of land on which peasants grew food for themselves, with a percentage of the harvest paid as “feudal dues” to the lord. This type of farming is largely subsistence farming, and cropping decisions were made based on what the peasant families needed to eat the following year. This is in contrast to modern market farming where cropping decisions are made based on market conditions, so that landowners will make as much money selling produce as possible (Waters 2007, pp. 37–41).

On the traditional subsistence-focused manors, the peasantry could not be dismissed from the land because of a poor harvest or the inability to pay customary dues. Rather, just like a parent, the feudal lord had a responsibility to keep the peasantry safe from enemies and fed, even when crops failed and normal feudal dues not paid. The expectation was that the following year might be better. They could not “fire” their peasants who, in the belief system and legal system of the feudal manor, “belonged” to the soil even if the harvest was poor. They could not even sell the land to another manor, unless the peasants could stay. Price-setting markets in labor, produce, and land were not found on the feudal manor (see Waters 2007, pp. 45–51).

In contrast, in the modern economy, there is a belief that the person who works the land and the person who owns the manor have different interests. In a modern labor market, workers are paid only when they are hired by an employer for whom they generate cash profits. In this market, labor can be bought and sold (and starve!). Land also can be bought and sold if the owner thought such a move was profitable. In other words, in the modern system, there is not an assumption that the lord, land, and the farmer are a single unit which

can be bought and sold. Rather they are seen as a single unit.

For the modern capitalist system to work well, Weber wrote, there needs to be a shared cultural belief that it is important to pursue money so that ever more can be purchased and consumed. So how do farms change from being a self-contained unit with fatherlike relationships between lord and farmer, to a modern farm where everything is negotiable in the marketplace? Weber was particularly interested in how peasants who lived on patrimonial manors where they would be taken care of by the feudal lord changed into a “workforce” which was responsible for sustaining itself by seeking a “job” which paid a cash wage.

The Protestant Ethic and the Spirit of Capitalism

Weber’s best-known work about the shift from the older feudal ethics embedded in feudal loyalty to a modern market economy is *The Protestant Ethic and the Spirit of Capitalism* (1904–1905). In this book, Weber described how farmers viewed work on subsistence farms where there was a belief that work was not only to satisfy day-to-day needs by growing only the amount of produce needed to feed the family during the coming year. They could then stop working to enjoy life, since there was no need to produce extra grain to sell, and indeed there was no large market where surplus grain could even be sold. This is in contrast to a modern capitalist farmer, where the goal is to produce as much crop as possible to sell (not to eat) and the producer sells into the global market and becomes as rich as possible. They may even grow industrial crops like flax, cotton, sugar beets, sugar cane, sunflowers, etc., which do not provide nutrition for the people who grow them, but which is sold at great profit in the world marketplace.

Here is how Weber described the difference between a traditional farming ethic and the ethic of capitalism in *The Protestant Ethic and the Spirit of Capitalism*:

...In [market-based] agriculture, for instance, the gathering of the harvest is a case where the greatest possible intensity of labour is called for, since, the weather being uncertain, the difference between high profit and heavy loss may depend on the speed with which the harvesting can be done...

...But a peculiar difficulty has been met with surprising frequency: raising the piece-rates [that peasants are paid] has often had the result that not more but less has been accomplished in the same time, because the worker reacted to the increase not by increasing but by decreasing the amount of his work. A man, for instance, who at the rate of 1 mark per acre mowed $2\frac{1}{2}$ acres per day and earned $2\frac{1}{2}$ marks, when the rate was raised to 1.25 marks per acre mowed, not 3 acres, as the the spirit of capitalism might easily have done, thus earning 3.75 marks, but only 2 acres, so that he could still earn the $2\frac{1}{2}$ marks to which he was accustomed. The opportunity of earning more was less attractive than that of working less. He did not ask: how much can I earn in a day if I do as much work as possible? but: how much must I work in order to earn the wage, $2\frac{1}{2}$ marks, which I earned before and which takes care of my traditional needs? This is an example of what is here meant by traditionalism. A man does not “by nature” wish to earn more and more money, but simply to live as he is accustomed to Whenever modern capitalism has begun its work of increasing the productivity of human labour by increasing its intensity, it has encountered the immensely stubborn resistance of this leading trait of pre-capitalistic labour. (Weber 1904–1905/1998, pp. 59–60)

Making the transition from traditional feudal manors to capitalist farms is a difficult one, but it is undertaken all over the world. In the process, though, the formerly self-sufficient farms are displaced and moved off their land and into the cities. Peasants typically suffered a great deal during this process, a process known as “The Great Transformation” (see Waters 2007, p. 47).

Weber's Writing About Ancient Roman Agricultural Society

Weber's use of agricultural examples in his writing reflected his long-term studies of agriculture in ancient times, medieval times, and in early twentieth-century Europe. In developing his points about the relationship between agriculture and society, Weber relied on reading original manuscripts in Latin, Greek, Hebrew, and modern languages. His earliest and most direct work about agriculture examined the legal structures that the Roman Empire developed so that the farmers, peasants, and slaves on the Roman plantations would grow enough food to feed not only

themselves but also the Roman cities where food could not be grown. To do this, ideas about the ownership of land, responsibilities to work for slave-masters, criteria for trading grain, and many other laws needed to be written and enforced. This process was described in his books *Roman Agrarian History* (1891) and later in *The Agrarian Sociology of Ancient Civilizations* (1909), which covered ancient civilizations such as Mesopotamia, Egypt, the Hellenistic world, and Rome.

Weber described how Rome conquered land with the sword and then followed up with the plow and laws about land tenure, agricultural labor, and land surveys. What emerged on the Roman slave plantation were barracks for slaves who were organized into groups of ten, and then presided over by “whip-bearers.” A legal system described who owned the land, how commodities could be traded, and what responsibilities and rights agrarian slaves had. Weber was particularly critical of the fact that the system created led to large plantations which became unwieldy and contributed to the decline of the Roman Empire. This system proved sustainable he write, but only as long as new captives could be enslaved. It broke down when there were no more lands for the Romans to conquer where they could capture more slaves (see Radkau 2009, pp. 72–73).

The ancient agrarian civilizations also informed Weber's writings about the nature of social stratification. For example, in Weber's essays about class-based antagonisms, he described how ideologies about cattle people and horticultural people developed in ancient times. This, he said, was particularly important when it came to understanding the development of credit and banking because land is a fixed commodity, while cattle is a mobile commodity – it walks away! As a result, cattle people and farms think differently about land ownership, water rights, and even banking. After all using land as collateral is fundamentally different than using cattle which can easily be hidden. Weber observed that the way that city-based creditors created and then monopolized credit markets, meant that rural people needed to in participate in the urban cash market. Thus, even though the farmers produced the food the cities needed, the establishment of

banking and debt actually turned the relationship around and made the cities more powerful than the countryside. In the end, an unequal relationship emerges, in which an ideology becomes the basis for domination of the rural farmers and herders, by the urban elites (Weber 2015, pp. 43–44). Such inequality even led to bread riots in ancient Roman cities. Later in the medieval ages, such inequality between city and rural farming areas led to hoarding, dumping, and other acts designed to manipulate food prices to the advantage of urban financiers (Weber 1921/2015, pp. 47–48).

Agrarian Reform in Eastern Germany in the Early Twentieth Century

Agriculture in eastern Germany was at the heart of a number of essays Weber was commissioned to write in the 1890s (see summary in Weber 1906/1947). These essays were sometimes commissioned by the German government, which was trying to bring the eastern part of Germany where there were still feudal manors (often called “*Junker* estates”) which had rapidly growing peasant populations. The *Junkers* wanted to move the peasants off the land and into labor markets so that they could plant crops which were profitable in world markets. But the peasants only wanted to plant the food they needed to eat in the coming year. So the peasants resisted, and the *Junkers* (and the German government) assumed that the peasants were too “lazy” to seek jobs in labor markets, because they continued to ask the government and *Junker* landlords for food in times of shortage. So, the German government sought ways to get the peasantry to participate in the rapidly growing cash economy, while the conservative peasants preferred to “simply live as accustomed to,” as Weber explained in the *The Protestant Ethic and the Spirit of Capitalism*. In this situation, Weber sarcastically noted that a subsistence farmer “who delivers his produce mainly to a place where the world-market price is least important – that is, to his own stomach – [was] the one most able to survive in the east” (quoted in Radkau 2009, p. 86). That is, the feudal lord and his peasants who consumed what they grew never sold their

product into the world market, were not sensitive to market prices, and still survived, even though their farms were unprofitable.

In his writing about the German peasantry, Weber was particularly interested in describing the changing nature of agricultural labor as land became scarcer, because the world market shifted to cash crops. Planting decisions he noted became based on market demand, not what went into the peasants’ stomachs. At its most stark, this meant that the peasantry’s potatoes were replaced with the inedible sugar beets of the distant sugar factory (Radkau 2009, p. 84). The peasantry then needed to make a wage so that they could buy potatoes in the marketplace instead of growing food themselves. Most tragically though, when they did not make enough money in the marketplace, they could of course starve, and this was no longer the landowner’s problem as it had been in feudalism, and it fell to the welfare programs of the government.

But of course, in the late nineteenth century, there were increasing demands for food needed by the booming marketplaces of the growing cities, irrespective of what the estates needed to feed their peasantry (Munters 1972). To meet this demand, there was a displacement of peasants, as the estates shifted to large-scale market-based agriculture, in which planting decisions were not made based on what people on the estate needed to eat, but on what the price of grain (or sugar beets) would be on the distant commodity markets, like those in Chicago, USA. The globalized economy was arriving!

Conclusion

Agriculture and the soil were central to Max Weber’s sociology. While this emphasis is best known from the *The Protestant Ethic and the Spirit of Capitalism* which described the shift from the ethics of the feudal peasantry to that of the modern market system, the soil in fact permeated Weber’s thinking for much of his career. In part, this was due to Weber’s deep understanding of ancient Roman agriculture that he developed early in his career. But it was also developed in the context of his own understandings of how

agriculture and farming people continued to play a role in how society changed rapidly from a feudal to capitalist economy in the nineteenth- and early twentieth-century Germany.

Meat: Ethical Considerations

[Omnivorism](#)

Introduction

Meat eating has been the norm in most human societies. Historically, it has not had many defenders, but this is probably because few thought that it was in need of defense. In the contemporary philosophical literature, however, the pro-vegetarian arguments are usually taken to be quite strong, and omnivores have assumed the burden of proof. The purpose of this entry is to

explain this shift by surveying the various frameworks that offer neutral or positive moral assessments of meat eating. After briefly tracing the evolution of these frameworks from the ancient to modern period, the entry outlines the three most prominent contemporary approaches. It closes by considering possibilities for future research.

Historical Perspective

Consider the perspective found at the beginning of the Hebrew Bible:

²⁶ Then God said, ‘Let us make humankind in our image, according to our likeness; and let them have dominion over the fish of the sea, and over the birds of the air, and over the cattle, and over all the wild animals of the earth, and over every creeping thing that creeps upon the earth.’ ²⁷ So God created humankind in his image, in the image of God he created them; male and female he created them. ²⁸ God blessed them, and God said to them, ‘Be fruitful and multiply, and fill the earth and subdue it; and have dominion over the fish of the sea and over the birds of the air and over every living thing that moves upon the earth’. (Genesis 1:26–28, NRSV)

The salient points are (a) that all humans are categorically different from all animals and (b) that the world has a certain order. Moreover, although the text permits weaker readings, it does seem that humans’ status as image bearers justifies – or at least explains – humans’ having dominion and the authority to subdue.

The points above, however, do not lead to the view that meat eating is morally unproblematic; to reach that conclusion, there must be a claim about the purpose (or purposes) for which animals were created. And in what immediately follows, the text indicates that they are not for food:

²⁹ God said, ‘See, I have given you every plant yielding seed that is upon the face of all the earth, and every tree with seed in its fruit; you shall have them for food.

³⁰ And to every beast of the earth, and to every bird of the air, and to everything that creeps on the earth, everything that has the breath of life, I have given every green plant for food.’ And it was so.

So subduing and having dominion over animals does *not* include consuming them, and in the view of some later biblical authors, there are hints that the world will be restored to this vegetarian

order (see, e.g., Isaiah 11:6–9). Nevertheless, it remains the case that the biblical tradition sanctions the consumption of meat: God says that all creatures are for Noah’s use after the flood (Genesis 9:1–3), and when Christians have reflected on this issue, they have used it not only to defend omnivorism but to put it forward as a good. For example, John Calvin (1509–1564), the French theologian and pastor, wrote these words:

For it is an insupportable tyranny, when God, the Creator of all things, has laid open to us the earth and the air, in order that we may thence take food as from his storehouse, for these to be shut up from us by mortal man, who is not able to create even a snail or a fly. (1554/1847, pp. 291–292)

Moreover, Jesus probably ate lamb (see Luke 22:14ff. in the light of Exodus 12:3) and fish (Luke 24:41–43), and he encouraged others to do so (Matthew 15:34–37; John 21:5–14). In Acts, God tells the Apostle Peter to kill and eat animals in a vision (Acts 10:9–16); Paul insists that there is nothing wrong with eating meat sacrificed to idols (1 Corinthians 10:25–26); and the author of 1 Timothy contends that abstaining from certain foods – i.e., meat – is evidence of having fallen away from the faith (1 Timothy 4:1–5). In the background, of course, are commitments to there being a fundamental difference between humans and animals, a divinely ordained teleology, and some form of theological voluntarism. Between these three factors, it is not hard to understand why there was no felt need to defend meat eating.

God moves into the background in Aristotle’s work (384–322 BCE), who maintained that humans are the *rational* animals; the “lower” animals, by contrast, lack this faculty (*Nichomachean Ethics* VI.2). The upshot of the difference is that man is ruled by reason, whereas animals are subject to “despotic” rule – i.e., they are governed by appetite rather than intellect. Aristotle goes on to claim that animals are better off if ruled by beings that *are* rational (*Politics* I.V). The capacity hierarchy apparently justifies a corresponding paternalistic hierarchy, though it remains to be shown that animals ought to be killed for food. This issue is addressed by the second part of his view – i.e., his natural teleology:

...a bare livelihood, seems to be given by nature herself to all, both when they are first born, and when they are grown up. [...] So] we may infer that, after the birth of animals, plants exist for their sake, and that the other animals exist for the sake of man, the tame for use and food, the wild, if not all at least the greater part of them, for food, and for the provision of clothing and various instruments. Now if nature makes nothing incomplete, and nothing in vain, the inference must be that she has made all animals for the sake of man. (*Politics* I.VIII)

So, since Aristotle thinks that the good for any being is found in actualizing its potential, he can conclude that the good for animals is found in their being used for our purposes.

This view faces two serious objections. The first is that even if Aristotle is right about there being a capacity hierarchy, it is not clear why this justifies a moral hierarchy based on species membership: it is very hard to identify a morally significant property (or even a plausible constellation of morally significant properties) had by *all* human beings – not just normal adults – that is not shared by at least some animals. The second is that, since Darwin, natural teleology has fallen on hard times. To be made respectable again, it will have to be naturalized. However, it seems very unlikely that it will be naturalized in a way that would provide the ethical implications that Aristotle needs. It is possible to view many of the historical discussions of meat eating as grappling – albeit implicitly – with one or the other of these problems.

Take, for example, a related view in the Greek Stoic Chrysippus (c. 279–206 BCE) (via Porphyry (234–c. 305) and with his help):

But, by Jupiter, the assertion of Chrysippus is considered by our opponents to be very probable, that the Gods made us for the sake of themselves, and for the sake of each other, and that they made animals for the sake of us; horses, indeed, in order that they might assist us in battle, dogs, that they might hunt with us, and leopards, bears, and lions, for the sake of exercising our fortitude. But the hog (for here the pleasantry of Chrysippus is most delightful) was not made for any other purpose than to be sacrificed; and God mingled soul, as if it were salt, with the flesh of this animal, that he might procure for us excellent food. (Bk 3, §20; 1823, p. 114)

Chrysippus' approach is also teleological – hogs are literally *for* humans – but he reverts to the

overtly theological position that Aristotle eschewed. Chrysippus does not explain why hogs are fit for this purpose, and Porphyry – an advocate for vegetarianism – does not press him on this point. Instead, and in keeping with his earlier criticisms of Zeno of Citium (c. 334–262 BCE), Porphyry takes the lacuna to be an account of how slaughtering an animal could serve its interests. Charitably, he goes on to quote Carneades (214–c. 129 BCE.) – a member and eventual head of Plato's Academy – who apparently maintained that “everything which is produced by nature, is benefitted when it obtains the end to which it is adapted, and for which it was generated” (Bk 3, §20). With Carneades' theory in hand, Chrysippus can insist that hogs *are* benefitted by their slaughter, since that is the purpose for which they were made. Thus he offers Aristotle's view with one major revision: there is no need to naturalize teleology, since it can be explained by way of divine intentions. However, Chrysippus doesn't provide the resources to explain why the moral hierarchy tracks species membership; there is nothing like image bearing in his account. And – at least in the extant fragments – Chrysippus offers no contrast between humans and animals that can account for them.

In *Summa Contra Gentiles*, Saint Thomas Aquinas (1225–1274) – an influential Dominican priest, theologian, and philosopher – supplements Chrysippus' teleological framework with the claim that animals have no intrinsic value:

...the very way in which the intellectual creature was made, according as it is master of its acts, demands providential care whereby this creature may provide for itself, on its own behalf; while the way in which other things were created, things which have no dominion over their acts, shows this fact, that they are cared for, not for their own sake, but as subordinated to others. That which is moved only by another being has the formal character of an instrument, but that which acts of itself has the essential character of a principal agent. Now, an instrument is not valued for its own sake, but as useful to a principal agent. Hence it must be that all the careful work that is devoted to instruments is actually done for the sake of the agent, as for an end, but what is done for the principal agent, either by himself or by another, is for his own sake, because he is the principal agent. Therefore, intellectual creatures are so controlled by God, as objects of

care for their own sakes; while other creatures are subordinated, as it were, to the rational creatures. [...] Through these considerations we refute the error of those who claim that it is a sin for man to kill brute animals. For animals are ordered to man's use in the natural course of things, according to divine providence. Consequently, man uses them without any injustice, either by killing them or by employing them in any other way. (Bk III, Pt II, Chap. CXII, § I and XII)

Aquinas' account removes the pressure to explain why the moral hierarchy tracks species membership; likewise, it relieves the need to explain why God fashioned them for human use. If animals have only extrinsic worth, then the arbitrariness of God's decision is not obviously problematic: if something had to serve human ends, there is no reason why animals shouldn't.

Aquinas doesn't offer much of an argument for the view that animals have no intrinsic value, but the demand for one probably would not have seemed reasonable. A tacit commitment to the no-intrinsic-value view appears to be present even among some of the ancient vegetarians, a number of whom gave up meat based on their belief in reincarnation. Take, for example, a passage from *The Lives and Opinions of Eminent Philosophers*, where Diogenes Laertius (third century) quotes Xenophanes (sixth to fifth century BCE) on Pythagoras (c. 570–c. 490 BCE):

They say that once as passing by he saw
A dog severely beaten, he did pity him,
And spoke as follows to the man who beat him:
"Stop now, and beat him not; since in his body,
Abides the soul of a dear friend of mine,
Whose voice I recognized as he was crying" (8.20).

At least in this passage, there is no suggestion that the dog would deserve moral consideration if it weren't occupied by Pythagoras' "dear friend." Likewise, in fragment 137, Empedocles (c. 495–435 BCE) criticizes the slaughter of animals for food:

Each slits the throat and in his halls prepares
A horrible repast. Thus too the son
Seizes the father, children the mother seize,
And reave of life and eath [*sic*] their own dear flesh. (1908, p. 62)

Here too, the challenge to meat eating is premised on these animals once having been people (indeed, the *relatives* of the meat eaters) – and *not* on anything about them as, e.g., sentient beings in virtue of which eating them constitutes "a horrible repast." The assumption that animals have no intrinsic value appears to be just beneath the surface. Moreover, this is not an assumption unique to the ancient and medieval worlds: it's also present in the work of René Descartes (1596–1650) and Immanuel Kant (1724–1804). Descartes was convinced of this because he maintained that animals are mere automata; he insisted that "[his] opinion is not so much cruel to animals as indulgent to human beings [...] since it absolves them from the suspicion of crime when they eat or kill animals" (1649/1991, p. 366). Kant, by contrast, did not deny that animals have mental lives, but he did believe (a) that their mental lives are impoverished relative to humans' and (b) that this difference explains why animals have only extrinsic worth:

The fact that the human being can have the representation "I" raises him infinitely above all the other beings on earth. By this he is a person [...] that is, a being altogether different in rank and dignity from things, such as irrational animals, with which one may deal and dispose at one's discretion (1798/2006, p. 15).

(The above passage permits a reading on which animals have so little value, relative to that had by humans, that it is permissible to treat them as though they had no intrinsic value at all. However, it's clear from other portions of Kant's corpus that only rational beings have intrinsic value, and – at least among earth's inhabitants – he takes rationality to be a uniquely human characteristic).

The Contemporary Conversation

In the contemporary literature on animal ethics, it is difficult to find philosophers who maintain either (a) that each and every human has some morally significant property that distinguishes her from any animal or (b) that in the objective order of things, animals exist for humans. Moreover, contemporary philosophers are much more likely

to the possession of properties like *being able to feel pain* or *having desires* to be sufficient for having some sort of moral standing. So, meat eaters end up on the defensive (see, e.g., Nozick (1983), Cohen (2004), and Williams (2006)).

There are three general approaches among those who make a case for the rightness of meat eating. Those taking the first maintain that meat eating is either compatible with or required by the moral theories that are usually used to defend vegetarianism. Those opting for the second offer contractualist defenses of speciesism. Those electing for the third argue from general considerations relating to the good of the environment as a whole.

Steven Davis (2003) represents the first approach. He argues that given the “least harm” principle that features in certain arguments for vegetarianism (cf. Frey (1983)), the best diet is one that includes the flesh of large herbivores. The problem with drawing the pro-vegetarian conclusion, he contends, is that it ignores the animal lives lost as a result of modern agricultural technology, e.g., field mice being crushed by the combines that harvest grain. These casualties could be reduced by allowing large ruminants to forage in and fertilize the fields, minimizing the number of times that machinery had to be deployed. Based on his calculations, this would cut the total loss of animal life by one third. Matheny (2003) raises some hard questions about the numbers in Davis’ argument, but the calculation-oriented strategy may still have merit. Consider the hordes of animals that would not exist were it not for the animal husbandry that supports the omnivorous diet. Frederick Ferré (1986) argues that if those practices could be altered so that animals lived subjectively pleasant lives (to include painless deaths), then the sheer numbers will undermine any straightforward utilitarian argument against killing them for food. Indeed, once these changes have been made, there may even be some obligation to consume them.

R. G. Frey (1983) takes a line like Ferré’s, although he seems to think that meat eating is morally permissible before any reforms have taken place. From a utilitarian perspective, he claims, there is an obligation to abstain from

meat eating only if so doing spares some animals from the suffering they would otherwise experience. But the existence of moral vegetarians makes no discernible difference to the practices of the meat industry: the sheer scale of modern factory farming makes it insensitive to the behavior of what is, ultimately, a very small number of consumers. So, there is no obligation to abstain from meat eating. Moreover, he argues that even utilitarians are free to say that, while animal lives are valuable, they are not as valuable as human lives, and hence it is possible for significant human interests to outweigh significant costs to animals. (He makes this last point in a defense of vivisection, but it clearly applies to omnivorism as well. Jack Weir (1991) uses roughly this idea to defend meat eating for those persons for whom a vegetarian diet would pose health risks.)

Finally, feminists like Kathryn Paxton George (1990, 2000) argue that the condemnation of speciesism involves an implicit commitment to sexism. She contends that pro-vegetarian arguments make assumptions about human dietary needs that are accurate only for adult males. Moreover, they assume – falsely – that people have equal access to the means to secure healthy vegetarian meals. She insists, therefore, that nothing more than “semivegetarianism” is morally required of women, children, the elderly, and those disadvantaged economically or by poor health.

The second group of philosophers is composed of contractualists. Roger Scruton (2006), for example, says that animals have no moral standing because they cannot participate in “the ongoing dialogue which binds the moral community” (59). To participate in this dialogue, a being needs to be – *inter alia* – self-conscious, free, rational, able to exhibit sympathy, able to accept obligations, and able to insist on their fulfillment (25–32). Scruton grants that this excludes those humans at the margins, but he replies that “it is part of human virtue to acknowledge human life as sacrosanct, to recoil from treating other humans, however hopeless their life may seem to us, as merely disposable” (43). Peter Carruthers (1992, 2011) takes a similar contractualist line, but he responds to the “humans at the margins” problem differently. He points out that, given the

purpose of the social contract, rational agents will not select rules that are not psychologically supportable, since that would undermine the ability of the contract to provide a safe, stable environment. And given people's strong attachments to infants, the senile elderly, and the severely mentally handicapped, they will not choose rules that do not presuppose moral standing for such individuals.

Scruton and Carruthers agree that contractors ought to give animals some moral consideration; what they deny is that contractors have reason to grant animals full moral standing. For Scruton, this is because animal death is involved in the realization of certain human goods – hunting, cooking, feasting, etc. (cf. Scruton (2004)). For Carruthers, this is because almost all animals do not have phenomenally consciousness mental states – a conclusion that follows from a number of higher-order theories of phenomenal consciousness; see Carruthers (2005) for details – and hence do not feel pain.

On the contemporary accounts considered thus far, a being's moral standing depends entirely on its intrinsic (nonrelational) properties. (For utilitarians, that value depends on sentience; for contractualists, it depends on a combination of sentience and various sophisticated cognitive capacities). The final strategy for defending omnivorism abandons this assumption, opting instead for an extrinsic (relational) theory of moral standing. Take, for example, J. Baird Callicott's (1989) "biosocial" view, which updates Aldo Leopold's (1949) land ethic. On this view:

...the good of the community as a whole, serves as a standard for the assessment of the relative value and relative ordering of its constitutive parts and therefore provides a means of adjudicating the often mutually contradictory demands of the parts considered separately for equal consideration (25).

Here, the "community as a whole" refers to the entire ecosystem. On this approach, everything in the ecosystem has moral standing, but a thing's having moral standing does not entail that it should not be killed. Hence, there is nothing inherently wrong with killing animals, since it is sometimes in the best interest of the environment to do

so (e.g., if the deer population is out of control, then culling the herd might be warranted). The biosocial view says, "not vegetables instead of animals, but organically as opposed to mechanico-chemically produced food" (36). (Pollan (2006) seems to have a similar position in mind when he discusses the role of animals in sustainable, small-scale agriculture. For an alternative theory of moral standing that combines intrinsic and extrinsic criteria, see Warren (1997).)

Future Work

Meat eating needs little defense, if any, given that (a) all humans are categorically different from all animals and (b) the world has an objective order. However, since neither assumption enjoys the philosophical currency it once did, the proponents of meat eating face an uphill battle. Their best bet is probably some combination of the contractualist approach and the environmental perspective. The contractualist approach offers a principled way of denying animals' moral standing, but it leaves open questions about the extent of the moral consideration that it is appropriate to extend to them. Callicott's biosocial view might provide the resources to resolve this problem. After all, science is only beginning to map the complicated webs of ecological dependencies that the planet supports. Should it turn out that the environment will fare best if people have a diet that includes the flesh of humanely and sustainably raised animals, then people may have a self-interested reason to be omnivores. And that, of course, is precisely the sort of reason to which contractors would attend.

Summary

This entry presents historical and contemporary perspectives on the ethics of meat eating. Many of the historical voices suppose (a) that all humans are categorically different from all animals and/or (b) that the world has an objective order. However, most contemporary philosophers do not make either assumption, so those who defend

meat eating tend to take one of three approaches. Those taking the first maintain that omnivorism is either compatible with or required by the moral theories that are usually used to defend vegetarianism. Those opting for the second offer contractualist defenses of speciesism. Those electing for the third give an environmental perspective.

Introduction

A variety of developments over the past century have produced the conditions in which eating and feeding are transformed from practices embedded in social or cultural relations into explicit medical practices. The rise of medical science, expansion of the pharmaceutical and food industries, escalating concern over diet-related diseases and conditions, and growing anxiety over infant and childhood development have contributed to a process of medicalization.

Medicalization is a sociological concept that analyzes the expansion of medical terminology, interventions, or practitioners into areas of the

life that were previously considered outside the medical sphere. For instance, undereating has previously been defined using theological language, as an act of fasting demonstrating a saintly character. Such practices are now understood through medical terms of anorexia nervosa, malnutrition, or general diagnoses such as “eating disorders not otherwise specified.” Individuals engaged in under- or overeating practices are increasingly defined by medical concepts (anorexia nervosa and obesity) and treated in medical spaces (hospitals, clinics, or rehabilitation centers) through medical interventions (pharmaceuticals, surgery, psychotherapy, or dietary regimens). Likewise, infant feeding (breast or formula) is understood as a practice that requires monitoring and instruction from medical practitioners. Further, eating in general is progressively invested with medical significance. Foods and diets are touted as possessing a therapeutic- or health-enhancing capacity that indicates an individual’s or population’s present and future health.

Due to the high regard for, and influence of, medical science in the West, medicalization studies primarily focus on Western contexts. Medicalization does have an impact on non-Western societies and the developing world; however, its influence emanates from Western biomedicine, industries, and policies. There is important work to be done in examining the process of medicalization in non-Western contexts; however, this entry is limited to the Western context (Hunt 1999).

To analyze the medicalization of eating and feeding, it is important to first sketch the theoretical and historical background of medicalization as a sociological concept. The relationship between eating and medicine is extensive. In order to focus the discussion, three examples are used – undereating, overeating, and infant feeding. This background focuses the analysis of the forces driving the medicalization of eating and feeding. Finally, in elaborating the influences and consequences of the medicalization of eating and feeding, some of the central ethical implications are identified and discussed.

Background

The concept of medicalization developed out of the anti-psychiatry critique in the 1960s. Thomas Szasz's *The Myth of Mental Illness* (2010), originally published in 1961, argues that psychiatry obscures the social with the psychological, transforming social behaviors and problems into symptoms of diseases that require medical intervention. According to Szasz, mental illnesses such as schizophrenia or attention deficit hyperactivity disorder are medical creations that mask the social problems individuals experience and justify coercive medical treatment. The work of Michel Foucault, Ivan Illich, Irving Zola, and Peter Conrad has been influential in advancing the concept of medicalization.

Philosophical debates over medical epistemology (theories of knowledge) play an important role in critical and ethical analysis of medicine (Stempsey 2006; Schwab 2012). Medicalization is associated with social constructionist theories of knowledge (Conrad 2007). Rather than contending the existence of a biological or pathological reality, medicalization studies argue that complex yet contingent social and cultural forces determine certain medical knowledge, categories, and definitions. Importantly, the social constructionist theory of knowledge does not argue that the phenomena described by medical categories are mere fictions, but that the medical categories are artificial constructs that misrepresent social phenomena as biological or psychological pathologies. This is evident in the example of undereating and anorexia nervosa.

Undereating and Anorexia Nervosa

Anorexia nervosa is an important case of the medicalization of eating and also demonstrates that the social constructionist approach does not minimize or trivialize the phenomena that are medicalized. Critics of the medicalization of anorexia do not discount the health implications of undereating, extreme weight loss, or food refusal (Bordo 2003). However, they argue that reducing the reality of anorexia to the biology or psychology

of the individual excludes the influence of social and cultural norms of the body, beauty, and femininity. Rather than isolating anorexia and undereating as medical phenomena abstracted from society, critics argue that anorexia and undereating need to be understood in the socio-cultural context in which they arise.

The relationship between hysteria and anorexia is helpful in elaborating the social constructionist account of medicalization. In the nineteenth century, hysteria was considered a meaningful medical diagnosis for women, demonstrated by an array of symptoms such as nervousness, increased or decreased sexual desire, food refusal, disobedience, or sleeplessness. Medical practitioners treated women who exhibited these symptoms through a variety of methods supported by highly esteemed research and evidence. However, by the twentieth century, hysteria was no longer recognized as a legitimate medical diagnosis. Some of the symptoms came to be regarded as the result of coercive social norms of femininity, while others were reframed as evidence for other conditions such as schizophrenia and anorexia (Brumberg 2000).

Establishing a psychological and/or biological cause for undereating and anorexia justifies medical interventions into the practice of eating. Through cognitive behavior therapy and medical nutrition therapy, medical professionals attempt to intervene in the psychological factors affecting eating practices. Using strategies such as food diaries and meal plans, medical professionals seek to control eating behavior in accordance with medically determined norms. In life-threatening situations, techniques such as forced or intravenous feeding can be employed. The implications of these interventions and the transformation of eating from a social and cultural practice into a medical act are discussed further below.

Overeating and Obesity

Since the middle of the twentieth century, large body mass has been viewed as medical problem and defined through medical terms such as obese or adipose. Overeating is regarded as the primary cause of large body mass and therefore targeted by

medicine. Importantly, medicalization is not an absolute process. Medical language and practices do not completely exclude moral, theological, or legal perspectives. Moral descriptors such as gluttony and weak-will remain entangled with medical conceptions; however, these terms are increasingly recast through medical language, such as “hyperalimentation,” “binge eating disorder,” or “night eating syndrome.”

The medicalization of eating in the context of obesity relies on a mechanistic conception of physiology. Energy intake (food) needs to balance with energy expenditure (exercise). Too much eating with too little exercise creates an energy surplus that leads to an increase in body mass. Obesity is commonly determined by the body mass index (BMI), which divides an individual’s body mass by the square of his or her height. A BMI greater than 30 kg/m² is defined as obese. Not considered a disease itself, medical professionals regard obesity a risk factor for diseases such as diabetes, heart disease, and types of cancer (Gard and Wright 2005). While there is a focus on increasing exercise, altering eating practices is regarded as the most obvious way to treat obesity. By creating a causal chain from eating to obesity to disease, medicine seeks to control eating practices as a means to control disease.

A number of medical interventions have been developed to control eating practices. Surgical interventions include jaw wiring (resulting in a liquid diet), intestinal bypass surgery (reducing the absorption of calories), gastric bypass surgery (reducing the size of the stomach and the volume of food it can hold), and gastric banding (implantation of a medical device to reduce the size of the stomach). These procedures enable medical control over the form, absorption, volume, and frequency of eating (Sobal 1995). Each procedure has a range of significant complications, such as malnutrition, anastomotic leakage, gastric dumping syndrome, infections, and incisional hernia. In addition to surgical interventions, pharmaceutical solutions have been sought to alter eating behaviors by producing the feeling of satiety and the suppression of appetite.

The use of direct surgical or pharmaceutical interventions is increasing; however, the most

common treatment to change an individual’s eating practices, and thereby reduce body fat, is through dieting. Dieting ordinarily occurs away from medical professionals and outside of medical spaces (clinic or hospital), yet they are imbued with medical significance and often supported by medical professionals. The increase of the medically prescribed or validated diet for obese and nonobese individuals suggests a general medicalization of eating (Sobal 1995). Through meal planners, food diaries, or commercial weight loss programs that offer meals created by nutritionists, eating is reframed as a medical practice that either fortifies health or increases the risk of obesity and disease.

The validity of the energy intake/expenditure conception is disputed from a variety of perspectives (Gard and Wright 2005). Some critics accept that obesity and overeating are a problem but argue that it is a social problem with causes located beyond an individual’s eating practices. These critics focus on social and environmental factors, such as urban planning and the increased availability of highly processed foods at the expense of fresh foods. At the other end of the spectrum, critics argue that the medical significance of body mass and overeating is exaggerated. They argue that individuals process and use energy at different rates and that larger body mass is not an indicator of overeating or disease but human diversity (Rothblum and Solovay 2009; Bacon 2010).

Infant Feeding

Infant feeding (formula, breast, or bottle-fed breast milk) has also been brought under the guidance of medical knowledge and practitioners. The vulnerability of infants and perceived long-term health impacts of infant feeding produce impassioned debate over the best feeding practice. The medicalization of infant feeding occurred with the development of pediatrics as a medical speciality and an emphasis on scientific motherhood from the 1840s onwards (Apple 1987). Prior to this, infant feeding was largely within the domain of mothers and midwives. Under these

circumstances, breastfeeding was the norm with rudimentary and unreliable substitutes used under particular circumstances.

During the 1840s, the infant food industry began producing infant formula and advertising their products in medical journals and women's magazines as a healthier and more convenient alternative to breastfeeding. Recognizing the commercial and medical significance of formula, medical researchers began working alongside and in competition with the commercial sector to enhance formulas. This period also saw a shift in childbirth from the home to the hospital. With childbirth occurring in hospitals, medical practitioners and pediatricians assumed control over infant health and encouraged mothers to use formula for its healthfulness and scientific basis. Mothers choosing to breastfeed were advised to supplement breastfeeding with formula to ensure the infant's health (Apple 1987).

It is important to note that formula is not the medicalization of feeding, with breastfeeding is as a nonmedical practice. The emphasis on the medical benefits of formula implied the medical insufficiency of breastfeeding. The reemphasis on breastfeeding that occurred during the late 1970s mobilized medical evidence to counter arguments that breast milk is inferior to formula. Extensive lists of health benefits of breastfeeding were published in magazines, medical journals, and popular books, claiming that breastfeeding protects against diabetes, asthma, and obesity and that it increases an infant's IQ (Wolf 2011). Further, research into the potential for diseases, toxins, and alcohol to transfer to an infant through breast milk did not dampen enthusiasm for breastfeeding but has led to medical professionals monitoring mothers to ensure that an appropriate diet and necessary care are used. Controversies over both formula and breastfeeding are part of, and contribute to, the process of medicalization of infant feeding (Van Esterik 1989).

Forces of Medicalization

Early critiques of medicine, notably Ivan Illich's *Medical Nemesis* (1975), argue that medical

institutions and practitioners drive the process of medicalization. Illich argued that the imperialist expansion of medicine to all areas of life – from birth to death – allows practitioners to control, dominate, and direct the lives of individuals. This thesis has provoked a counteraccusation that critics of medicalization are given to conspiracy theories and “doctor bashing” (Conrad 2007). The extent to which nineteenth- and early twentieth-century medicine sought to control life is debatable; however, it is clear from recent examples that medicalization has been driven by forces that do not fall exclusively within the domain of medicine. The forces that have promoted the medicalization of eating and feeding include, but are not limited to, professional medical organizations, advocacy groups, private industry, government policy, and the media.

National and international medical organizations have significantly influenced the process of medicalization. For example, the American Psychiatric Association and the World Health Organization produce diagnostic manuals that shape the definition of disease and influence policymakers, clinicians, researchers, insurance companies, and pharmaceutical companies. Conditions such as hysteria, homosexuality, masturbation, obesity, erectile dysfunction, and attention deficit hyperactivity disorder have been included or removed from such manuals over the past 50 years, arguably due to nonmedical influences (Conrad 2007).

Consumer and patient advocacy groups are increasingly influential forces on medical research and the medicalization of eating and feeding. Advocacy groups use public awareness campaigns, lobby policy makers, and provide research funding to increase the profile of an existing condition or to promote a condition or practice not yet recognized as medical. For example, the La Leche League International and the National Alliance of Breastfeeding Advocacy raise awareness about the health benefits of breastfeeding and campaign for policies to encourage breastfeeding (Wolf 2011). A variety of other advocacy groups foster public understanding for diet- and eating-related conditions, such as the National Association of Anorexia Nervosa and Associated Disorders, the

Obesity Action Coalition, or the National Foundation for Celiac Awareness.

Advocacy groups are also influential in the de-medicalization process. In response to obesity, the National Association to Advance Fat Acceptance and the Fat Underground critique the medicalization of overeating and advocate for the acceptance of body diversity (Rothblum and Solovay 2009). These groups draw on the exemplars of the Gay Liberation Front and the Gay Activist Alliance, who were instrumental in the removal of homosexuality from the 1974 edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders*.

Industries also play a significant role in the medicalization of eating and feeding. The food, weight loss, pharmaceutical, and insurance industries all play distinct yet overlapping roles. For instance, many pharmaceutical companies own the medical devices used in gastric banding. It is profitable for these companies, as well as the surgeons and clinics, if more surgeries are performed. However, health insurance companies often limit coverage to surgeries for medical rather than cosmetic need. Therefore, the medicalization of obesity, and the control of eating practices as a treatment, is promoted by a network of actors. These include advocacy groups (Obesity Action Coalition), pharmaceutical industry representatives (Johnson & Johnson), and medical organizations (American Society of Bariatric Surgery; Conrad 2007). The food industry is also an important force in the medicalization of eating. While food companies are careful not to market products as pharmaceuticals, there is an increasing trend to market products with health claims, blurring the distinction between food and medicine. This process transforms the act of eating from a pleasurable or social act into a medical and health-benefiting act.

Government awareness and public health campaigns drive shifts in the way conditions and practices understood. For example, the US Department of Health and Human Services' National Breastfeeding Campaign from 2004 or the many campaigns around the Western world targeting overeating and obesity have promoted medical conceptions of eating and feeding

practices. These campaigns attempt to alter public perception of eating and feeding and raise awareness of the medical relevance of such practices.

The media are enormously influential forces yet difficult to quantify. From reports on food safety scares to the importance of superfood, the media (in their increasingly varied forms) shapes public understanding of the medical significance of eating practices (Lupton 1996). The media helps to popularize nutritional research as well as introduce the public to terms such as omega-3 or folic acid. The media are used by, and amplify the impact of, the forces described above.

Ethics and Consequences of Medicalization

The analysis of medicalization can be a purely descriptive task. A study examining the medicalization process may attempt to describe shifts in the way a condition or practice is understood and refrain from valuing one understanding over another. However, the majority of research into the process of medicalization adopts a critical stance. The transformation of social or cultural phenomena into medical conditions is often considered to have harmful consequences for individuals and society. However, some scholars suggest that medicalization produces both positive and negative consequences (Purdy 2001; Parens 2011). Considering the potential for medicalization to produce mixed consequences, philosophical and bioethical analysis of the process is needed (Sadler et al. 2009). The examples above demonstrate a number of consequences that require ethical consideration. Consequences vary between conditions, practices, and the sociocultural situation in which they occur; yet a number of common consequences can be isolated.

First, the lives and practices of women are disproportionately medicalized (Bordo 2003; Conrad 2007). Women are burdened with the responsibility to ensure their own eating practices accord with medical direction, but they are also positioned through the forces of medicalization as responsible for the eating and feeding practices of infants, children, and partners. While medical

authorities target certain eating practices of men, particularly in relation to obesity, male overeating is often regarded as an indicator of masculinity.

Second, the process of medicalization obscures sociocultural contingencies. In treating under-eating and anorexia as a medical condition, the analytic lens is focused on the biological and psychological. This focus excludes the influence of social and cultural norms on eating practices and perception of the body (Bordo 2003). Ironically, failure to acknowledge the influence of norms of femininity and the body has consequences for health, as the foundational causes are not addressed. The failure to critique social and cultural norms also has implications for the just and fair ordering of society.

Third, in framing problems such as undereating and anorexia as a pathological condition of the individual, medicalization has an individualizing effect. Instead of addressing harmful social norms, political discrimination, or environmental factors and critiquing those that promote them, medicalization reduces the cause of a particular phenomenon to a blameless and morally neutral pathology. Positioning the individual as sick can be beneficial as it reduces individual responsibility and stigma, particularly when an individual is suffering from a biological pathology. However, if the “disease” is social, or entangled with the social, rather than biological or psychology, then focusing on the individual also removes responsibility from societal and political influences.

Fourth, medicalization can remove stigma and limit individual responsibility for a problem; however, it can also reinforce and amplify individual responsibility and choice. Rising concern over the ramifications of the perceived “obesity epidemic” has led to eating practices and the bodies of people defined as obese to be characterized as irresponsible (Gard and Wright 2005). The amplification of individual responsibility and choice is also evident in the medicalization of infant feeding. Mothers’ feeding decisions are positioned as evidence of responsibility (or irresponsibility) and determiners of the long-term health of the infant (Wolf 2011). In these instances, medicalization burdens individuals with the responsibility for

outcomes that are not necessarily within the individual’s control or choice. This scenario raises deep philosophical questions of moral responsibility for actions partly determined by uncertain or uncontrollable factors (Nagel 1991).

Fifth, medicalization enables medical control of aspects of life that do not require control. The fat acceptance movement argues that bodies medically defined as obese are instances of human diversity, like height and eye color. Further, they contend that people with a larger body mass do not necessarily eat more than people considered to have a normal body mass (Rothblum and Solovay 2009). From this perspective, medical control and surveillance of eating as it relates to body mass are unnecessary and harmful, especially when irreversible surgical interventions are employed.

Sixth, increased medical surveillance over daily life is a substantial consequence of medicalization. Examples can be home visits from dietitians and nutritionists to ensure medically appropriate meals are prepared or the use of nurses to monitor infant development and instruct mothers on how to care for their child in accordance with best medical knowledge (Apple 1987). The provision of medical assistance is an important part of a just society. However, if assistance is provided for non-medical conditions, the medicalization of these conditions can reduce individual autonomy and create an unnecessary dependence on medical authority.

Finally, in addition to the effect on specific practices and conditions, the medicalization of eating as it relates to dieting and health promotion can transform eating and feeding from a social and cultural practice into medical therapy (if the individual is ill) or enhancement (if the individual is well). This shift disrupts and transforms relational and communal activities, such as the meal and food preparation, into medical acts. Further, in magnifying the medical effect of eating practices on the future health of an individual or infant, the medicalization process has the potential to produce anxiety and unease without the necessary evidence to support claims about the future effect of eating practices on health.

Summary

The medicalization of eating and feeding is a process through which eating and feeding practices are transformed from social and cultural phenomenon to medical acts. The process of medicalization occurs through political, social, and medical contingencies that shape human behavior and interpret certain practices or conditions as causes or symptoms of disease. The examples of undereating, overeating, and infant feeding demonstrate the complex web of influences involved in the medicalization process. A number of ethical concerns result from this process, including the reduction of culturally significant practices to medical ends, gender inequality, masking social injustice, obscuring social and environmental determinants of health and disease, burdening individuals with responsibility for conditions beyond their control, and increased medical surveillance.

Metaphysics of Natural Food

[Compound foods](#); [Organic foods](#); [Philosophy of nature](#); [Whole foods](#)

Introduction

The adjective “natural” is often employed to characterize a food or beverage, and consumers tend to associate a positive value to it (Siipi 2013). The understanding of the adjective, however, varies across countries, and, in some circumstances (e.g., in the United States), “natural” is considered vague to the point that it cannot be defined and its usage cannot be strictly regulated. The *Codex Alimentarius* – a chief collection of internationally significant standards, practices, and regulations pertaining to food, which is maintained by the FAO (Food and Agriculture Organization) – does not acknowledge the term “natural” as significant to characterize a product; it contains, instead, a standard for organic foods. At any rate, as a first approximation we may define the adjective “natural,” when used in connection to food labels, as “produced or existing in nature.” That which is natural, that is, is seen in contrast with that which is artificial, where the definition of “artificial” is “made by human work.” When the human work in question is a chemical synthesis, then the product is said to be “synthetic.” Synthetic products are made from parts or elements that do not occur in nature or, at the very least, from parts or elements that do not occur independently in nature. A material formed by chemical synthesis has a characteristic chemical structure that was, at some point, invented within a specialized laboratory; that is, the parts or elements of the material are combined to form a whole whose chemical structure does not occur spontaneously.

“Natural” Foods

Two sorts of foods can be bestowed the “natural” label: *whole* and *compound* natural foods (cfr. also Bozicevic 1987). Whole foods are those that can exist also spontaneously – that is, without human intervention – such as honey, milk, apples, or blueberries. Though by now we have well-developed techniques for the production of some of these foods, the production does not crucially alter the identity of the food. The current British

labeling system for natural foods, which is inspired by this twofold distinction, can be useful to illustrate it a bit further. A whole food that is natural is a food that is natural without qualification. This is when a food has not been subject to any modification during its production and packaging, other than those procedures that would make it suitable for human consumption. For instance, a natural dairy product is a food manufactured from milk alone, with the possible aid of traditional cultured bacteria that are necessary for the fermentation process. A natural milk yogurt, under this understanding of “natural,” is a milk yogurt obtained solely from milk and *Lactobacillus bulgaricus* and *Streptococcus thermophilus*; no additives, such as preservatives, flavorings, or colors are allowed.

Between whole and compound foods, there are some ingredients whose naturalness needs to be assessed on separate grounds. Belong to this list of ingredients additives and flavorings. Thus, a natural additive is one deriving from a natural whole food, or from a natural organism, by a traditional process (e.g., sugar extracted from sugar cane) or by a process that does not alter its naturally occurring chemical structure.

The second sort of natural food is compound foods made from natural ingredients. These foods differ from whole foods in that, without human intervention, they would not exist on their own. An apple pie, a portion of spaghetti with pesto, and a salad of red beets and walnuts are examples of this second sort of foods. Compound foods derive their naturalness from their ingredients. Compound foods, that is, are “natural” when all of their ingredients are natural. Thus, a natural bread would be a bread whose ingredients are all either whole natural foods or natural flavorings and additives. While “artificial” products require human intervention, some artificial foods are made from natural ingredients and are hence regarded as natural. “Natural,” when applied to foods – or, at least, to compound foods – does not stand for an entity that occurs spontaneously in nature. On the other hand, “synthetic” products not only require human intervention, but they must be arrived at by means of chemical synthesis performed by humans.

An alternative labeling system has been in use in Israel. In this case, the naturalness of a product is defined by means of a list of 33 processes. The processes identify the only allowed manners of modifying a whole natural food. The processes are all physical treatments, such as freezing, drying, cleaning, and blending; none of the allowed processes are chemical modifications.

Some countries have remained skeptical with respect to the meaningfulness of the adjective “natural,” when used to describe a food. In the United States, the Food and Drug Administration (FDA) agency discourages producers from using it. The agency attempted to define natural foods in 1991 but gave up in 1993, noticing that the term “natural” was too vague and indefinite. A similar attitude is held by the United States Department of Agriculture (USDA), which has standards to define organic produce, but no standard for natural produce. Of course, both the FDA and the USDA disapprove of, and can take action against, claims that falsely describe a product, including claims that falsely portray a food as natural. But without some standards for naturalness, it is difficult to hold producers accountable for misleading consumers. A notable example in the United States is chicken meat labeled as “all natural” even when it has been injected with a saline solution that increases its weight up to 25%. Consumers and institutions, such as the Center for Science in the Public Interest, have objected to this use of the adjective “natural,” without significant governmental responses.

Finally, “natural” can also be employed in complex expressions, such as “natural goodness,” “nature’s way,” or “naturally better;” it may also be substituted or implicitly implied by terms such as “real,” “genuine,” or “pure.” Most legislation dissuade or prevent the usage of such expressions and terms, which can easily misguide a consumer because of their ambiguity. On the other side of the spectrum, the use of “natural” to describe some products – mostly fresh products – is subject to no specific labeling restrictions. When it comes to such products, the consumer is left on her own to determine the naturalness of the food.

Natural Misunderstandings

The adjective “natural” can have several misleading implications. Four of them are considered here (cfr. Siipi 2013 for a further discussion). The first feature is *nutritional suitability or superiority*. Natural foods are not necessarily nutritionally suitable, or more suitable than their non-natural counterparts, however. Some natural foods, such as sugar and lard, need be used in moderation and may not be suitable for someone’s diet. Also, synthetic foods, such as vitamins and amino acids, may be as nutritious as their natural counterparts.

Secondly, “natural” may imply some *health claim* (cfr. Siipi 2013). While it is the case that, in some states, the adjective indicates that the food has not been substantially altered or processed, this is not sufficient to establish a general health claim. For instance, it may be believed that “natural” equals “nontoxic,” but this is not always the case. Depending on the soil or the specific characteristic of the product, a food may be toxic even when natural. Also, some natural whole foods – such as sugar and lard – and some natural compound foods – such as lasagna or apple pie – may be unhealthy, if eaten without moderation.

Thirdly, “natural” may suggest the *lack of human influence*. However, this is not the case for all natural compound foods. Moreover, in the case of natural whole foods that are farmed, the product is obviously the result of human effort.

Finally, “natural” may suggest *authenticity* (See entry on “► [Authenticity in Food](#)”) or *familiarity*. Not all natural foods, however, fit these adjectives. Consider, for instance, the case of natural breads. As the number of ingredients found within a loaf of bread grows high, and their processing becomes increasingly cumbersome, the tendency is not to regard the bread as familiar or authentic, even when all of its ingredients qualify as natural.

Often there is a gulf between the legal understanding of a term, the scientific understanding of a term, and the term’s everyday meaning. Terms used to characterize foods are no exception; in fact, they offer several prominent case studies. “Organic” (See entry on “► [Trade Policies and](#)

[Organic Food](#)”) is another term whose usage is often misleading. In its scientific understanding, organic stands for a living organism, a part of a living organism, or that which is derived from an organism. However, in its everyday and legal usage, the term stands for the product of a plant or an animal grown without synthetic pesticides, synthetic fertilizers, hormones, antibiotics, and meeting all other standards issued by the country in which the product is grown. Obviously, there is a major difference between the meanings of “organic” in the two contexts. But, manufacturers of products other than agricultural ones are under no obligation to specify their understanding of the term.

Natural Foods and the Metaphysics of Nature

The difficulties in defining and regulating the use of the adjective “natural” to describe a food are part and parcel of a broader metaphysical debate over the proper understanding of the term. The idea of nature is perhaps one of the most abused ideas in common usage, not only from a commercial point of view but also ideologically and theoretically. One’s view of the proper understanding of natural foods depends on one’s underlying metaphysical approach to nature. Helena Siipi (2008) has proposed a threefold classification based on whether naturalness is grounded in a certain history or in a property or in a relation. Such classification is complementary to the one proposed here, which is based on four classic metaphysical positions concerning nature. For each position, its place in the debate over natural foods is indicated.

1. “Nature” derives from the Latin root “gna,” which stands for *that which generates*. In fact, the predicate “nasci,” to be born, has the same root. The very first position regards nature as that from which everything is born. On this metaphysical understanding, any food ultimately counts as natural. This position backs up the opinion of agencies, such as the FDA, who hold that “natural” is too broad and

vague of a term to be useful in describing some foods as possessing a characteristic which other foods lack.

2. The second position, of Aristotelian descent, claims that *any individual thing has a nature of its own*. Thus, the nature of this apple is different from the nature of that yogurt. Also in this case, the adjective “natural” is of little use on food labels. However, individual natures can and should be captured by food labels. The definition of items provided by governmental agencies, then, should try and pin down the fundamental kinds of foods that there are. Such kinds reflect biological differences (e.g., the variety of an apple tree or the genetic makeup of a seed of corn) and also mirror geographic similarities (See entry on “► [Geographical Indications, Food, and Culture](#)”) and particular methods of production (e.g., authentic specialties or fair trade products) (See entry on “► [Fair Trade in Food and Agricultural Products](#)”). This definition is especially important for understanding compound natural foods. An apple pie, as noted above, is natural only if its ingredients are natural. But it takes the right ingredients in order to make an apple pie; that is, the nature – in the Aristotelian sense – of the apple pie needs to be respected as well in order for the resulting product to even count as an apple pie.
3. A third position defines natural as that which is *spontaneous*. To be emphasized here is the lack of an ordering will on a crucial phase of the process of generation. Thus, a golden delicious apple, despite being the product of a grafted tree and of human effort, is still spontaneous, as its characteristic genetic makeup is not the outcome of human intervention: it occurred spontaneously. Vanilla extract counts as natural, under this definition, because its chemical structure is contained in the vanilla beans. Vanillin produced by chemical synthesis, instead, is not natural.
4. According to the fourth position, natural is opposed to *artificial*: natural is that which is not produced by humans. In some cases, that which is natural could also be produced artificially. Thus, for instance, ocean waves can be

natural or artificial. This position cannot be applied to natural compound foods, which are the outcome of recipes and – as described above – are derivatively natural in that they derive their naturalness from their ingredients. However, the position plays an important role in the labeling of natural whole foods. A whole food, which is delivered without altering its key characteristics, is natural; for instance, an apple that is washed and cleaned, before being delivered to the market, is still natural. On the other hand, a whole food which is processed and substantially altered, or a food which is produced by chemical synthesis, is not natural.

Each of the four metaphysical positions on nature helps to shed some light on the debate over natural foods. The upshot is that the understanding of the adjective “natural,” when applied to food, can hardly be reduced to one metaphysical schema. Some skepticism regarding the usefulness of the term in picking out a genuine characteristic of a food remains.

Summary

The entry employs the conceptual tools of metaphysics to critically study the adjective “natural,” when utilized to characterize a food or beverage. There is some skepticism regarding the usefulness of the adjective in picking out genuine characteristics of a food. While some countries, such as the United States, have abstained from issuing specific regulations regarding the use of the term “natural” to describe a food, others – e.g., England and Israel – do have such regulations. The entry first draws a distinction between the application of the adjective to whole foods and to compound foods. Hence, four typical misunderstandings of the term are flagged. They comprise circumstances in which “natural” is taken to imply – respectively – nutritional suitability, a health claim, lack of human influence, and authenticity or familiarity. Finally, four classic metaphysical positions on nature are introduced. The positions jointly support the different facets that the adjective “natural” takes in describing a food. They

also reveal how the adjective “natural,” when applied to food, cannot be reduced to one meta-physical position.

Introduction

Cow's milk, and the products therefrom, has been a staple in the human diet dating back 7500 years or more. Pure, healthy, and unadulterated, this has been the image of milk for a long time. In more recent years, milk and its production have come under increasing scrutiny. Pasteurization of milk and the movement in medicine to have single healthy foods to treat disease led milk to its rise to the top of the food pyramid. It did not hurt that milk helped to reduce the incidence of rickets at a time when incidence in urban areas was staggeringly high. In recent years, however, milk has been implicated in developed countries with diseases such as obesity and heart disease, environmental issues, and animal welfare and ethics issues. On the other hand, movement to natural and organic food has led to issues concerning food safety, and whether or not we were even meant to consume milk. Production of milk and ethical issues involved are the subject of this entry.

History and Symbiosis

Man and cow have enjoyed a long symbiotic relationship. Whether man domesticated cow or cow domesticated man, the two have shared a long history (some 7000–8000 years at minimum). Man provided feed, protection, and shelter. Cattle provided draught power, meat, and something new: **milk**. Whether it was fermented into cheese or yogurt, or drank fresh, milk helped mankind to become civilized, no longer nomadic (Valenze 2011). A symbiotic relationship implies that there is benefit to both parties in the relationship. It is relatively easy to argue that this was true in the beginning. Mankind has been changing the relationship with the cow since the beginning, many arguing that the relationship has shifted heavily in favor of man.

The modern day cow no longer resembles that cow of old and may have become little more than a milk machine to some. An argument is made that very few “real cows” exist in the wild today, suggesting that the symbiotic relationship still exists, even though the relationship has changed.

The perception that the “product of the dairy animal, milk, is a pure product” is common today, but that has not always been the case (Valenze 2011).

As dairy cattle, water buffalo, goats, sheep, camels, and other animals have been domesticated, it is very likely that the domesticated animals had better feed than their undomesticated counterparts. More milk than was necessary for offspring was produced. This milk was recognized as something that could be collected and fermented in stable food products and later on be consumed fresh. Domestication of the cow probably aided in populations going from hunter-gatherers to agriculturally based (Curry 2013).

Milk Value

There are a growing number of people who believe that people should not drink milk because it is not natural for any other mammals to drink milk after a young age (Lanou 2009). Almost all infants and young children produce lactase, which is needed to break lactose down. While a large portion of the world's population lose the ability to make lactase, making them intolerant, there is still about 35% of the population that can produce lactase throughout adulthood. Curry (2013) cited work that indicated that a single gene mutation occurred about 7500 years ago in Hungary that allowed for lactase persistence into adulthood. Researchers indicated that this single mutation resulted in 19% more fertile offspring, clearly an evolutionary advantage. This clear advantage would only work if populations had access to milk into adulthood. Separate mutations were believed to occur in West Africa, the Middle East, and Southeast Asia (Curry 2013) which allowed for lactase persistence in those areas. As the gene mutation meant that people had to have fresh milk available, it clearly indicates that at least some people were designed to consume milk.

Milk has long been considered a pure unadulterated food and there has been a concentrated effort to keep that image. Cheese and fermented foods have long been enjoyed. But milk really has only enjoyed this reputation for about 200 years.

Before that refrigeration and spoilage issues kept milk from gaining a “super food” status, milk was consumed as fermented product such as cheese or yogurt. Toward the end of the nineteenth century, events occurred that put milk on the top as good food (Valenze 2011). Louis Pasteur developed the “Pasteurization” method that allowed milk to keep bacteria counts lower longer. This, along with standardization of milk regulations and refrigeration, allowed for longer transport into the cities. As cities grew in population, spread of serious illnesses also became a growing concern. Scientists and doctors became interested in treating the ill with only the simplest, purest foods. Nutritionists nutritionally defined milk as having protein, fats, and carbohydrates. Milk was also observed to contain large amounts of calcium and phosphorus. Once scientists also discovered vitamin D was in milk as well, milk’s reputation as a pure healthy food was sealed. Rickets was a large problem in the early nineteenth century, and it could be severe and debilitating (Holick 2006). Discovery of vitamin D’s role in calcium and phosphorus metabolism and its role in rickets led federal authorities to regulate the addition of vitamin D (actually a hormone) to milk as milk is not an excellent source of vitamin D by itself. Rickets in the western world had just about been eliminated, but more recently there has been a small resurgence of rickets as some parents have discontinued the feeding of milk, without understanding the need of replacing lost minerals and vitamins. Also, as we have removed fat from milk, it is federally mandated that vitamin A, as well as vitamin D, be added to milk.

Is Milk Good or Bad?

During the last 20–30 years, however, milk has begun to lose its prestigious position at the top. Milk began to get the reputation that it was not good for one’s health. Saturated fats, excess protein, and even the calcium and phosphorus came under the scrutiny of researchers, and there started to be a body of research that did not support all of milk’s purported benefits. Research claimed linkages to cancer, diabetes II, and multiple sclerosis,

Milk Production: Ethical Issues, Table 1 Is milk good or bad for our health?

Health concern	Milk is good
Prostate cancer ^a	No
Ovarian cancer	No
Type 1 diabetes	No
Multiple sclerosis	No
Otitis media	No
Colorectal cancer ^b	Yes
Cardiovascular disease	Yes
Ischemic and hemorrhagic stroke	Yes
Reduced hypertension	Yes
Obesity control	Yes

^aFrom Lanou (2009)

^bFrom Givens (2012)

among other harmful effects (Lanou 2009; Table 1). On the flip side, there has been a good amount of research that milk has been good for certain health conditions including hypertension, vascular disease, and obesity (Givens 2012; Table 1). It should be noted that many studies for and against milk have confounding factors. Many milk drinkers tend to have a higher caloric and meat intake. It can be difficult to tease these effects out of the study. A positive correlation between two effects does not necessarily mean that one causes the other. Weaver (2009) indicated that milk is one of the most economical sources in the USA for many limiting nutrients, an important factor for many of the nation’s poor, many of whom are women and children. In addition, while it is known that a vegetarian diet can replace an omnivore diet, vegans may have a higher risk of bone fracture (Weaver 2009). Weaver (2009) noted that for women aged 19–50, the three cup per day food recommendation met women’s calcium and magnesium recommendations; without milk products in the diet, 44% and 57% of calcium and magnesium requirements, respectively, were met.

Raw Versus Pasteurized (Sterile) Milk

Pasteurization of milk was one of the main forces that allowed milk to be transported farther, kept longer, and be a safer product, rising to the top of

the food chain. Other methods of sterilization have been developed. Systems such as ultra-high temperature (UHT) treatment are popular in the EU. In recent years, movements such as buying natural foods and only locally grown foods have made the consumption of raw milk (unpasteurized milk) increasingly popular (Claeys et al. 2013; see ► [Natural Food](#)). The idea of consuming milk raw is that heating milk destroys some of its nutritional value. Concomitant with the increased consumption of raw milk, however, have been an increase of food borne illnesses (Claeys et al. 2013). Despite this, the raw milk movement is growing. Claeys et al. (2013) do a nice job of addressing some of the potential benefits of raw milk (Table 2). Clearly consumers of raw milk must be concerned with increased bacteria in the milk, some harmful. The purpose of Pasteurization is to kill most of the bacteria, so this issue is not a concern. Other purported benefits are identified in Table 2. Raw milk often does have a different taste. The UHT treatment definitely changes taste. Laws on how much fat is in milk are federally regulated in the USA. Also cow diet can change the flavor of milk and does affect the fatty acids that are in milk, some of them proven to have beneficial effects. Milk that is pasteurized is not

often linked to food borne illness. Raw milk is increasingly connected. This need not be the case, however, as proper handling of raw milk can mitigate bacterial contamination.

Social Consumerism

Gareth Enticott (2003) asked an interesting question: why in a time of increased concern over food security is raw milk consumption growing? Granted, this is not a large movement yet, but it does suggest that there may be some conflict of definition of risk here between lay and science-based views, and what goes into those definitions. Enticott (2003) did a case study on a small farming community in England. He used people in this village to understand why they continued to drink unpasteurized milk despite government safety warnings to the contrary. Consumption of raw milk underscored that risk assessment of food choices is not always rational and scientifically based assessments. This is not to say the assessments are not logical however. Consumption of milk was closely linked to community, nature, and rural, not just the individual. When urban consumers purchase raw milk, it is

M

Milk Production: Ethical Issues, Table 2 Comparison of raw milk to pasteurized milk (Adapted from Claeys et al. 2013; not all data used and in some cases word alterations)

Nutritional factor	Raw milk	Pasteurized milk
Nutrients	No alteration of nutrients	Heating modifies functional properties of proteins, but little effect on nutritional quality. Lysine decreases 1–4% upon heating
Antimicrobial properties	From colostrum; not usually consumed in raw milk. Increasing interest for antimicrobial and antiviral properties. Must be clarified	Destroyed upon heating, but these immunoglobulins cannot be absorbed by human intestinal tract
Commensal lactic acid bacteria	Production limited at refrigerated temperatures. Degrades milk rapidly at higher temperatures	Irrelevant because milk is sterile
Probiotic bacteria	Does not contain enough beneficial bacteria to be of use. Growth inhibited by refrigeration	Destroyed by sterilization
Milk enzymes	Most enzymes destroyed by gastric digestion. No credible research to support theory that milk enzymes in raw milk are beneficial	Enzymes destroyed by sterilization
Milk lactose	Low glycemic index, prebiotic properties, promotes calcium and magnesium absorption and is an important energy source for infants	Same in sterile milk as raw milk

likely that many of the same values are in play. It is incumbent on the raw milk producer to protect these values, as well as the safety of the milk.

Organic

Many consumers believe that organic is natural (possibly raw milk) and that the animals are raised outdoors on small farms. All these are misconceptions. The USDA organic label comes with regulations about what can be fed to cows and does not allow the use of antibiotics, among other things (see ► [Organic Food Policy](#)). Farms with thousands of cows have been labeled organic and supply excellent care for their animals. Some small farms assure neither the quality of their product nor the welfare of their animals. Organic also does not mean not pasteurized. Sundrum (2001) indicated that organic farming is a production method with high requirements for management qualification and high quality of the production process. Whether consumers are drinking raw or pasteurized, organic or not, they need to be confident of the terms used to describe the milk they drink, and they need to have a certain level of knowledge of risk they are taking with the consumption of milk. Organic milk is not necessarily any more animal welfare friendly than conventional farming (Knaus 2015). The level of skill and education of the managers does play a role in the quality of the milk.

Ethical Veganism

Tristram McPherson (2014) attempted to make the case that if you drink milk (or consume milk products) you must also be willing to set fire to a cat for your ethical values to remain consistently logical in his essay on ethical veganism (see ► [Veganism](#)). McPherson argues that there is something intrinsically morally wrong with making an animal suffer. Therefore, if you would not make a cat suffer by setting it afire, you should also not drink milk, because getting milk from a cow ultimately causes that cow to suffer. Few people of good moral integrity would consider

setting a cat on fire morally acceptable, while a majority consumes milk. So what is the difference? As McPherson noted, milking a cow is not intrinsically bad. He makes the assumption that cows must suffer during their lives on a “factory” farm and that they suffer a cruel death, thus the equivalency of setting a cat on fire. McPherson’s assumptions about the cat are probably true, but the assumptions he uses for the cow are not necessarily true (see ► [Dairy Production: Ethical Issues](#)). Many of the current issues are being resolved through technical advances and a better understanding of the animal. The argument that we cause suffering to dairy cows should not be strong. When a cow reaches the end of her productive life, it is true that she is slaughtered, but unlike the cat in this equation, the cow can and should be humanely slaughtered. This is not to say that there are no problems in the dairy industry. Many dairy animal welfare issues remain. Dairy cows are subject to metabolic diseases associated with increased milk production, and there are housing, calving, and environmental issues associated with dairy welfare, among other issues. Much work has been on these issues and science and consumer issues remain an issue. Many of these “cow” issues, including bovine somatotropin (growth hormone), are dealt with elsewhere (see ► [Dairy Production: Ethical Issues](#)). The fact that problems remain (that can and should be fixed) does not mean that the process itself is immoral.

Whether we consider the cat and cow to have moral rights or we have moral duties to them, in both cases we are making an informed decision on the taking of the lives of these animals. If we concede that the cow is humanely slaughtered for the purpose of meat, then would not the death of the cow be considered much less egregious than wantonly setting the cat on fire? Whether you believe animals have rights and are moral agents with a vested interest in their lives or are not is an argument beyond the scope of this entry but is germane to this discussion.

McPherson (2014) furthers his case for veganism by stating that we are not killing animals if we adopt a vegan diet. Unfortunately, this is simply not true. Davis (2003) estimates that many more animals would be killed if we adopt veganism,

than if we retain a mixed animal and plant-based diet. He reports other studies that have concluded that the number of animals killed in crop-based agriculture is large. Animals such as mice, rabbits, voles, opossum, rock doves, wild turkey, and other ground-dwelling animals are all killed in the process of producing field crops. Davis estimates that the numbers of animals killed by converting to a vegan diet would result in millions of more animals being killed per year than when consuming a mixed diet. The argument is made that there is no intent to kill these animals during food production, but do the means justify the ends? Also once you know that animals are killed during harvesting, can the claim be made that the act is still not intentional? There is much that can be pondered when a consumer picks up that glass of cow's milk or chooses to drink soy milk instead to drink with their cookie. People have to eat, so a choice must be made.

Conclusion

Is milk a pure unadulterated foodstuff or a food that is increasingly plagued with questions of safety, community values, and morality? Humans and cows have enjoyed a symbiotic relationship for thousands of years, with some humans even having a genetic mutation to allow for the consumption of milk through adulthood. Now that food is no longer a problem to obtain in developed countries, some have begun to link milk with diseases of the affluent, such as diabetes and cancer, although other data find beneficial effects of milk consumption. Some people have joined back-to-nature movements, consuming organic products and raw milk. Some of the values involved with this movement deal with community, environment, and moral values, despite some increased health concerns with the consumption of raw milk. Milk as a product is also linked with cow welfare and the resultant need to harm animals. Both systems involved with drinking milk or veganism involve the death of animals. Humans must eat however, and a difficult choice still must be made at this time.

Modern Slavery in Agriculture

Mark Stein
Salford University Business School,
Manchester, UK

Synonyms

Exploitation; Farmworker rights; Forced labor;
Migrant workers; Trafficking; Violence

Introduction

Slavery as a legal status recognized under national laws was abolished almost everywhere in the world in the course of the nineteenth century. However, forms of forced labor have continued all over the world – to a greater or lesser extent in different countries and with varying degrees of toleration by government.

Miers (2003) provides a thorough overview of the persistence of forms of slavery and forced labor during the twentieth century. More recent discussions of modern slavery are provided by Kara (2017) and Kotiswaran (2017).

Forced labor describes a situation in which a worker performs work or services involuntarily

and under a threat of some form of penalty. There is considerable potential for goods produced by forced labor to end up being sold in developed countries such as Europe or North America:

Complex supply chains with multiple tiers stretching across continents and jurisdictions make it a challenge to ensure decent working conditions for all workers along the supply chain. The risk of forced labour is highest in lower tiers where there is little visibility and where there is the most vulnerable and socially excluded workforce. However, abuses can occur in any part of the supply chain and in any country. Every business needs to consider how and where it can be affected by slavery. Modern slavery is perceived to be more widespread than previously thought and is often to be found at the farthest reaches of the supply chain. (Skrivanovka 2017, p. 3)

Modern slavery very often includes movement of people for the purposes of exploiting their labor – trafficking (Skrivanovka 2017, p. 3).

ILO Indicators of Forced Labor

In 2012 the ILO (International Labour Organisation) published a booklet setting out Indicators of Forced Labour, which is intended to help “front-line” criminal law enforcement officials, labor inspectors, trade union officers, NGO workers, and others to identify persons who are possibly trapped in a forced labor situation and who may require urgent assistance. The indicators represent the most common signs or “clues” that point to the possible existence of a forced labor case (ILO 2012). The indicators are:

- Abuse of vulnerability
- Deception
- Restriction of movement
- Isolation
- Physical and sexual violence
- Intimidation and threats
- Retention of identity documents
- Withholding of wages
- Debt bondage
- Abusive working and living conditions
- Excessive overtime

The booklet provides detailed commentary to help assess whether the worker is indeed a victim of forced labor:

The presence of a single indicator in a given situation may in some cases imply the existence of forced labour. However, in other cases you may need to look for several indicators which, taken together, point to a forced labour case. Overall, the set of eleven indicators covers the main possible elements of a forced labour situation, and hence provides the basis to assess whether or not an individual worker is a victim of this crime. (ILO 2012, p. 3)

Workers may be vulnerable to forced labor for a variety of reasons including:

- Dependency on employer for immigration status, food, work, housing
- Fleeing conflict, natural disaster, displacement or persecution
- Language barriers
- Membership of a particular ethnic group
- Gender, age or disability
- Family relationships
- Debt (Skrivanovka 2017, p. 8).

Global Slavery Index

The 2016 Global Slavery Index is produced by the Walk Free Foundation and the International Labour Organisation. It estimates that 45.8 million people are subject to some form of slavery in the world today. The Index presents a ranking of 167 countries based on the proportion of the population that is estimated to be in slavery.

Those countries with the highest absolute numbers of people in slavery are India, China, Pakistan, Bangladesh, and Uzbekistan. Several of these countries provide low-cost labor that produces consumer goods for markets in Western Europe, Japan, North America, and Australia.

The countries with the lowest estimated prevalence of slavery by the proportion of their population are Luxembourg, Ireland, Norway, Denmark, Switzerland, Austria, Sweden and Belgium, the United States and Canada, and Australia and New Zealand. These countries generally have more economic wealth, score higher on government response, have low levels of conflict, and are

politically stable with a willingness to combat slavery.

A Growing Problem in Europe

A recent report by the Group of Experts on Action against Trafficking in Human Beings expressed concern that trafficking of persons for labor exploitation appears to be growing throughout Europe: “While there are considerable variations in the number and proportion of labour trafficking victims among countries, all countries indicate an upward trend of labour exploitation” (Council of Europe 2018, p. 8).

In the EU agri-food sector, “the exploitation of workers who move within or into the EU has become a quite profitable but unethical business. . . exploitation in this sector not only of illegal foreign entrants but also those with legal status. . . People trafficking, forced labour, health and safety violations, financial exploitation, housing abuses, lack of holiday and/or sick pay, daily dismissals and other violation of workers and human rights are endemic” (Zawojcka 2016, p. 38).

A list of organisations campaigning against Modern Slavery is given in Table 1.

International Agreements

International agreements opposing forced labor, human trafficking, and modern slavery are reviewed by Kotiswaran (2017) and Kara (2017).

The UN’s Agenda 2030 Sustainable Development Goal number 8, section 8.7 specifically refers to the issue of forced labor: ending modern slavery and human trafficking, including child labor, in all forms by 2025.

National Legislation Attempting to Combat Modern Slavery

For an overview of national laws, which can be used to combat forced labor and modern slavery, see Kotiswaran (2017).

In 2015 the UK passed the first law specifically aimed at combatting modern slavery – the Modern Slavery Act – which included a requirement that companies above a certain size should report on their efforts to eliminate slavery from their supply chains.

The UK Modern Slavery Act has been criticized for the weakness of its requirements and the perfunctory nature of most company reporting in response to this Act – indicating that most companies do not attach serious importance to eliminating slavery from their supply chains (LeBaron and Rühmkorf 2017).

Case Studies

There are many instances of products entering developed countries food markets where there are strong reasons to believe that they have been produced by forced labor.

Under-Researched in Management Literature

Crane (2013) remarks that scant attention has been paid to the phenomenon of modern slavery in the management literature. He argues that modern slavery is not an aberration but a natural part of present economic arrangements. His article shows how “enterprises that deploy slavery take advantage of the macro-institutional conditions that permit the practice to flourish in the face of widespread illegality and illegitimacy.”

UK: Vegetable Growers Employing a Migrant Workforce

New (2015) builds upon Crane’s arguments through a case study of labor practices in UK

vegetable growing, arguing that the overwhelming power of supermarkets over their suppliers has meant relentless pressure for lower prices which has in turn shaped labor practices.

His case study relates to the English county of Cambridgeshire, where many Eastern European migrants are employed in vegetable growing. During 2014 a local multiagency investigation called Operation Pheasant identified 19 cases involving allegations of human trafficking and over 200 involving alleged cases of illegal gang-master activity. By the end of 2014, this resulted in the “rescue” of over 80 people from exploitative labor arrangements, the revocation of five gang-masters licenses, with two illegal gang-masters being jailed, and one of the revoked license holders receiving a suspended prison sentence. The extensive press coverage of the operation and its outcome revealed the distressing and intimidating conditions in which the workers were operating. Most were involved in leek production for sale in UK supermarkets. All of these supermarkets have well-established and well-articulated antiforced labor policies; all would have no trouble in complying with the requirements of US or UK transparency legislation. But these abuses evidently carried on without the supermarkets doing anything to stop them.

Overall, the case provides a compelling illustration of the logic of Crane’s model; at least in part, it is the supermarkets’ conduct which gives rise to the desperate economic conditions that in turn provide a context of increased likelihood of modern slavery (New 2015, p. 10)

Seafood from Thailand

There have many published accounts of modern slavery in the production of seafood in Thailand

and elsewhere in south east Asia – such as Bales (2016), Yutaka et al. (2018).

In Thailand, the fishing and seafood industries contributed \$6.6 billion to exports in 2014. The sectors employ more than 600,000 people, including 302,000 registered migrant workers. In recent years investigations confirmed widespread practice of slavery, trafficking and violence on fishing boats and at onshore processing facilities. The European Union threatened in 2015 to ban fish imports from Thailand unless it cleaned up the industry. The military government did take some steps to try to improve worker's rights. In March 2018, the International Labour Organisation released a new survey, based on interviews with 434 employees within this industry (ILO 2018). The report concluded that fishermen in Thailand remain at risk of forced labor, and the identity documents and wages of some continue to be withheld. However, conditions overall had improved, both on fishing vessels and at seafood processing plants onshore.

Researchers asked about seven indicators of forced labor, including abusive working conditions, excessive overtime, and the withholding of wages and identity documents.

They found employers often complied with the new rules, including paying fishermen a minimum wage and issuing contracts. But they also noted strong indicators of forced labor, especially among migrants from Cambodia and Myanmar. Withholding of wages is still a problem – 24% of fishermen in the survey reported waiting many months for pay. One in three fishermen said employers kept their identity documents to prevent workers from leaving. The picture was more positive ashore – just 7% of seafood processing workers said documents were withheld, and none reported wages being held back.

Overall, 29% of fishermen had not experienced any indicators of forced labor; that was also the case for 56% of workers at seafood processing plants.

USA: Fair Food and Florida Tomato Farms

The Fair Food Coalition was launched in 2011 to address substandard wages and working conditions in US agriculture:

In the extreme, farmworkers have faced situations of modern-day slavery – according to the definition of forced labor and high standard of proof required under federal law. In these instances, workers have been held against their will, with the threat or actual use of violence, and forced to work for little or no money. Several of these cases have been successfully prosecuted by the US Department of Justice over the past decade (Fair Food Standards Council 2015, p. 4)

The large number of immigrant workers in US agriculture – whose right to be in the country is tied to a particular job for a specific employer – has promoted abusive employment practices (Barrios 2013; Southern Poverty Law Center 2013).

The Fair Food Program (FFP), which grew out of the Coalition of Immokalee Workers' (CIW) Campaign for Fair Food, brings together workers, consumers, growers, and retail food companies in support of fair wages and humane labor standards in the agricultural industry. This Program is a leading example of the Worker-driven Social Responsibility approach, where workers play a leading role in the definition, monitoring, and protection of their rights, and retail brands commit to support fair food through their purchasing.

An account of FFP's early struggles against abusive and illegal labor practices – amounting to virtual slavery – is given in Scheiber (2017).

Major US food companies which now support Fair Food include: Ahold USA; Aramark; Bon Appétit Management Co; Burger King; Chipotle; Mexican Grill; Compass Group; The Fresh Market; McDonald's; Sodexo; Subway; Trader Joe's; Wal-Mart; Whole Foods Market and Yum Brands.

Since its launch in 2011, Fair Food has brought about major reforms across the 35,000 acres of the \$650 million Florida tomato industry. In June 2015, the Programme expanded to tomato growers in six other states and to Florida growers of peppers and strawberries.

Protest demonstrations are held outside the offices of food retailers who refuse to join the Fair Food Programme (Bonhomme 2018).

Mitigating the Worst Abuses

Publicity

Forced labor almost always happens outside the public eye. Publicity can trigger consumer boycotts and push government bodies to take action to enforce laws against forced labor. (See Thailand case study above.)

Actions by the law enforcement authorities in the country where the food is produced

The law can be deployed to assist migrant workers

Very often however it is deployed to reinforce the position of their employers and suppress any opposition by employees to the manner in which they treated.

In Thailand – for example – the government has been pushed to intervene to improve working conditions by the threat of an international boycott of Thai seafood.

Public Procurement Policies

Public procurement policy makers can and should take steps to ensure that food they purchase was not produced by slaves. In practice this will require a deliberate effort to ensure that suppliers can verify that at every stage in the production process the food has been produced at workplaces with acceptable labor practices (Chartered Institute of Purchasing & Supply 2016).

Swedish local authorities are leaders in good practice here – sending representatives to Thailand to check out workforce conditions for food purchased there.

Promote Labels and Third Party Certification of Compliance with Human Rights Guarantees

Slave Free certification is one alternative <https://slavefreetrade.org/>.

Another and more widespread alternative is to purchase food bearing the Fair trade mark www.fairtrade.org.uk. The elimination of slavery is a requirement of the Fair Trade Producer and Trader Standards. Fair trade requires everyone who buys, sells, or processes Fair trade certified products from the raw commodity to packaging to comply with these standards.

Help and Advice to Migrant Workers

The Ethical Trade Initiative recommend a variety of ways in which vulnerable workers can be given additional assistance:

- Provision of legal advice on rights and immigration status.
- Information and access to support organizations that can act on behalf of vulnerable workers or advocate in their interests (trade unions, NGOs, migrant worker organizations, community groups)
- Specialized support for vulnerable workers, including women, young workers, workers with disabilities
- Provision of language classes
- Access to advice on financial and debt management
- Provision of alternative housing options (Skrivanovka 2017, p. 9).

Promotion of Trade Union Organization Among Vulnerable Workers

An outstanding example of the sort of initiative which is needed relates to Thailand where a collection of seven leading Nordic food companies financially assisted by the Swedish government have commissioned the educational technology company QuizRR to develop training tools to teach migrant workers about their employment rights and responsibilities. The hope is that this will promote worker organization and dialogue between workers and employers which will lead to better wages and working conditions (Nordstrom 2018).

Blockchains: Digital Technology Making Supply Chains Transparent

Blockchain technology is a secure, decentralized, distributed digital ledger that stores relevant data regarding any kind of transactional history. It is a shared, transparent database that is verifiable by all parties – and it cannot be altered. An early adopter of blockchain technology in seafood supply chains is a London-based NGO, Provenance. It has pioneered a system that traces pole and line-caught skipjack and yellowfin tuna in Indonesia from catch to consumer. This pilot project

suggests that blockchain has great potential for improving working conditions.

When the fish is caught, an RFID tag is attached. Local fishermen then use handheld devices to scan and upload the digital information to the cloud. These data then lodge itself in Provenance's blockchain ledger, creating a permanent record as the fish passes through each stage of the supply chain, from traders and suppliers to processors and canners, all the way to end consumers.

The technology can also be used to protect workers. Hitherto the murder at sea of enslaved workers has often gone undetected. A blockchain allows a unique data identifier to be linked to any person, making that individual visible and traceable, thus holding their employers accountable for that workers' safety and well-being. Recent advances in biometrics allow for the creation of unique worker ID databases, which can be monitored by businesses, NGOs, and regulatory agencies.

Posting a worker's contract on a blockchain creates transparency around wages, work schedules, and job requirements. Blockchains retain unalterable records of transactions, including payment of wages. By having access to records of digital cash payments or transfers into digital wallets, other stakeholders can be assured workers are being paid the right amounts, on time.

Remote monitoring of working conditions and the physical well-being of workers can now be done in real time, with the use of wearable devices, connected via the Internet-of-Things (IoT). Capturing this kind of data can prevent physical beatings, deprivation of food and water, sexual abuse, and instances of workers being killed and thrown overboard (Capri 2018).

Reforming National Migration Strategies to Reduce the Number of Insecure and Illegal Workers

There is a very clear connection between restrictive immigration policies and labor market demand being met by an increasing number of illegal and insecure employees, who are highly

exposed to exploitative labor practices (Lewis et al. 2015).

Any political move to liberalize immigration policies would be likely to reduce the number of workers most vulnerable to such exploitation.

However, this reform is in most countries becoming an increasingly distant prospect.

The political trend throughout the developed world has been for increasing electoral success for politicians opposing any liberalization of immigration controls.

Conclusion

Modern slavery in agriculture is a very serious problem, with worldwide effects. The countries where it is most prevalent produce food which is then exported in very substantial quantities to developed countries. Unfree labour is also found in agriculture within developed countries such as the USA, UK and European Union. A large number of organisations are campaigning against such slavery (Table 1). However international agreements and national legislation which purport to combat modern slavery have limited effectiveness. The development which has most potential to combat such slavery is the promotion of trade union organisation among low paid workers in agriculture. Block chain technology also has a role in making supply chains more transparent.

Molecular Gastronomy

Vivian Liberman
Bal Harbour, FL, USA

Synonyms

Food science; Modern cuisine; Molecular cooking; Progressive cuisine

Introduction

Molecular gastronomy is a scientific field that studies the changes food products go through during the process of manipulation. These physical and chemical processes take place due to the impact on the molecules of the food as it goes through the different stages of cooking. In more recent times, molecular gastronomy has had a different meaning. It has become known as a movement led by chefs who introduce innovative techniques in cooking to diners around the world. This entry will follow the history of the discipline and the movement, mention the key people involved in making it known, and look at the ethical questions that arise from all perspectives of the discipline: ingredients, preparations, and marketing.

History

The field of “molecular gastronomy” began in 1988 by two scientists, Nicholas Kurti and Hervé This,

who began working with the natural processes of food. They noted the physical and chemical changes the food underwent during its preparation and manipulation (Koppmann 2009). Kurti and This were looking to answer some of the most common questions of food preparation: How did food react to heat and why did it react that way? What other changes did food go through during the different stages of its preparation? In the beginning, the field was about the discovery of why changes occurred when food was exposed to common stages in every day food preparation. It had nothing to do with creative cuisine (This 2005).

The creators of the field of molecular gastronomy argue the field began with the use of fire to cook food. The exposure of food products to this treatment caused it to change physically. These physical changes took place because of the modifications in the molecular structure of the foods. Before Kurti and This began to study these evolutions, there was not a complete understanding of what exactly was causing the food to be transformed. Trial and error and observation made creations possible. An anonymous text from the second century BCE makes reference to fermented meat, and a later Apicius text from the fourth century BCE mentions making a liquid with animal parts and water that illustrates the beginning of making a basic stock, a food preparation still common today, and the base to many traditional French culinary creations that form the foundation of modern culinary arts and cuisine. In addition, most French culinary texts are laden with recipes that illustrate molecular gastronomy at its best since the beginning of their publication. Famous classic sauces such as a Hollandaise created by French Chef Auguste Escoffier are classic examples of food transformation in a chemical and physical form using friction and temperature to cause an emulsion. All of these examples allow This to prove that though molecular gastronomy is a new field of study, the aspects of food that it studies have been occurring since the beginning of the use of fire (This 2005).

Kurti and This were disappointed that people did not know why food was transformed through cooking. They decided to not only research but also teach others about their discoveries. Food undergoes chemical and physical modification

with the use of different elements through its processing and manipulation. In spite of the unavoidable use of molecular gastronomy within cuisine and cooking, most cooks prepared food without a conscious understanding of what happened to it on a molecular level. Disappointed by the lack of interest of food from this perspective, Kurti and This set out to identify all of the aspects and spread knowledge about them. Many years later, after a successful spread of the existence and importance of the field by its creators, it was added to the curriculum of the University of Paris in 1996. After Kurti's death in 1998, This continued to teach about the field but made one slight adjustment; he changed the name from molecular and physical gastronomy to just molecular gastronomy. He believed this name would be shorter and explained the physical changes reflected due to the molecular restructure that occurred within the foods throughout their life stage (This 2005).

In his PhD dissertation, Hervé This listed five aims to the field of molecular gastronomy. They were “to collect and investigate old wives’ tales about cooking; to model and scrutinize existing recipes; to introduce new tools, products and methods to cooking; to invent new dishes using knowledge from the previous three aims; and to use the appeal of food to promote science” (This 2005). This took the science into a new direction. A lot of publicity about this science was created and that led to the affiliation of many chefs within France and, later also, within the rest of Europe, who set out to create new recipes and food preparations that led to a cutting-edge, scientific form of food that was innovative and good to eat.

Molecular Gastronomy in the Twenty-First Century

Since the late 1990s, molecular gastronomy began to be recognized worldwide as a movement in a modern take to food. In 2001 French schools began to experiment with flavors. This successful venture led Canadian and French schools to integrate the teaching of molecular gastronomy within the curricula of the culinary programs. Many professorships were created around the world in

places such as the Netherlands, Argentina, Canada, and many other countries to continue to spread the knowledge of molecular gastronomy. The discipline, as being taught in culinary schools, differs from the original, introduced by This and Kurti. Molecular gastronomy, as a modern movement, focuses on innovative food preparations based on the more thorough understanding of the physical and chemical changes caused by food manipulation and the merging of ingredients. Kurti and This's molecular gastronomy did not focus only on food preparation; it was based on studying the changes of the food's physical and chemical states through their life cycle. Therefore, according to This, it is the scientists, not the cooks, who are molecular gastronomists, since they spread the knowledge of the science (This 2005).

The field of molecular gastronomy changed cuisine forever. Many chefs became interested in finding out why food reacts the way it does through the process of cooking. Chefs are interested in the work done by This and have joined forces with scientists to learn more about how they can create great dishes by understanding the physics and chemistry behind the food. Many dishes, concepts, and restaurants have opened, featuring foods, where the conscious application of scientific techniques transforms food into exciting culinary creations. Wylie Dufresne told Harvard students, doing things just because or because they had always been done that way was okay for a young chef, but as a more mature professional, he wanted to find a more precise reason as to why things happened. Opening his restaurant was an opportunity for him to continue to learn and find out the real reasons why changes in food occur (Brenner and Dufresne 2010). Restaurants such as elBulli, The Fat Duck, WD-50, and Alinea, among others, are recognized worldwide and not only prove to be exciting but also have become known as the pioneers of a new dining experience (Barham et al. 2010). Some restaurant chefs who use modern techniques label themselves as molecular gastronomists; others have rejected the title, claiming they are chefs. The fundamental elements of being chefs and serving great food are not dependent on the

use of modern techniques; instead, it is about using the best possible ingredients and preparing good food (Barham et al. 2010).

The molecular gastronomy movement has spread worldwide, and some chefs have been collaborating with Harvard scientists to demonstrate how the understanding of science can transform culinary tradition. The class, *Cooking and Science*, is meant to use food as a way to illustrate molecular transformations and allow for a better understanding of scientific concepts. The course is filmed in its entirety and available to viewers on YouTube free of charge. The scientists teach the theoretical portion of the course. The chefs demonstrate the preparation of dishes featuring the molecular changes mentioned in the theoretical portion of the class. However, these demonstrations include the modern preparation of the dishes; new ingredients are introduced in the form of powders, and more advanced technology plays a role in the cooking process. This illustrates not only how molecules change but also how science and technology impact the culinary field. On the lesson “Meat Glue Mania” on November 8, 2010, Professor Michael P. Brenner, professor of applied mathematics and applied physics, teaches students about complex chemical changes. Professor Brenner claims these changes can be as common as the Maillard reaction and caramelization, processes normally seen in the browning of meat or preparation of caramel. He also claims one of the challenges with these complex changes is they are not very well understood by scientists.

However, complex changes can also take place to create new foods. One of the ways these new creations can take place is with the use of transglutaminase; this compound glues two protein molecules together with a covalent bond between amino acids. As an illustration of the theory, Wylie Dufresne, chef of WD-50 in New York City, uses meat glue to adhere one filet of codfish onto another to create a thicker filet that will have a perfect shape that he can cook more evenly. This new creation reflects how the two existing protein molecules adhere to each other. Without the powdered meat glue, which he makes into a slurry to create a more even coat, this reaction would not be

possible. However, the understanding of molecular structure of foods has allowed Dufresne to create more modern takes with this product, including shrimp, tofu, and peanut butter pastas, which use meat glue to re-gelatinize the products into sheets (Brenner and Dufresne 2010).

Ingredients in Molecular Gastronomy: An Ethical Dilemma?

In the popular New York Times Magazine Essay “Unhappy Meals,” Michael Pollan begins to warn consumers about eating industrialized food. He asks consumers to avoid foods that are either unfamiliar or unpronounceable. Many of the ingredients added to processed foods have been incorporated into them to increase their shelf life and make the process of fabricating these foods less expensive. In addition, these foods substitute whole foods or, as Pollan calls them, real foods. The hydrogenized, high-fructose, maltodextrin and xanthan gum creations have been the center of an epidemic of health deterioration and disease in the United States and other countries using “Western diets” (Pollan 2007). Some of these ingredients, independently, are not harmful. However, their use in the foods suggests highly processed creations that contain other ingredients of lesser benefits (Pollan 2007).

Some of the ingredients utilized to “molecularize” food are common to food labels of supermarket conventional foods. In his lecture on complex chemical changes, Professor Brenner states that all of the chemicals he lists in his lecture change the flavor of foods depending on the amount of the chemical present in the foods. He also says: “...what is interesting about these chemicals is you can’t go to the grocery store and buy them, it is not like salt. . .” (Brenner and Dufresne 2010). However, many of these chemicals are produced through the process of cooking, not on the addition of a chemical; these flavor compounds are created by different combinations of food products and are also dependent upon the rate and temperature the food is being cooked. So, not all unpronounceable ingredients are additives; in addition, not all additives are

fabricated chemicals; some are extracted from natural sources (Brenner and Dufresne 2010).

Rachel Zemser, a culinologist, claims chefs “stole” the creations of the true food scientists: the people who originally created all the varieties of modified food starches and the equipment (centrifuges, freeze dryers, etc.) used by many chefs today. They use all of the techniques and ingredients and receive more fame from these creations than the scientists working for years to create them. She adds that chefs such as Ferran Adria, Wylie Dufresne, and Grant Achatz should become “real” molecular gastronomists. She defines this as a person who uses their creations for the improvement of societal food issues of every day consumer goods, rather than the creation of a modern dish within a restaurant targeted to just a few (Zemser 2010).

The ingredients Zemser talks about are identified as powders within the movement of molecular gastronomy (Zemser 2010). These are also the unpronounceable ingredients such as maltodextrin and xanthan gum, which Pollan tries to steer consumers against (Pollan 2007). Will Goldfarb, pastry chef and owner of Will Powder, one of the few distributors of powders in the United States, on his website, explains the source of the ingredients and their use. Stabilizers, emulsifiers, and spherification ingredients, just to name a few, are featured on his site and product list and are also elements of his own menu creations (Goldfarb 2012). The powders are sourced from natural sources, extracted, and sold as powders. Professor Brenner and Wylie Dufresne use transglutaminase, which is naturally produced by soil bacteria (Brenner and Dufresne 2010). In the powdered form, these ingredients cause transformations from the natural state of the foods, giving life to the foams, gels, capsules, and other shapes and textures common to the menus of the restaurants that brought molecular or modernist cuisine to life (Brenner and Dufresne 2010).

In his article “Incredible Edibles,” Lanchester claims Colonel Sanders’s cuisine is just as molecular as that of Ferran Adria because they both undergo textural and physical transformations through cooking (Lanchester 2011). Modernist cuisine uses some of the same ingredients used

as preservatives and texture modifiers within flavored milk. In the past few years, British Chef Jamie Oliver has been on a campaign to decrease obesity in the United States and teach people how to cook. One of his biggest battles in the food revolutions of West Virginia and California was the consumption of flavored milks at schools. He claims chocolate milk has more sugar than soda and in general is a bad addition to the diet of a child (Oliver 2010). Usually, chocolate milk labels feature the following: partly skimmed milk, vitamin A, palmitate, vitamin D, sugar, cocoa, artificial flavor, carrageenan, cellulose gum, and guar gum. The carrageenan added to the milk gives it a richer, silkier texture (CBS News Canada 2005). Carrageenan is also used within modernist cuisine; the purpose of adding carrageenan to restaurant food is to create gelled sauces and jellies (Goldfarb 2012). It is not just about the powders or the technique. Wylie Dufresne says all food is transformed scientifically even without the addition of powders. His cooking style is traditional food that has been impacted by the understanding and use of science to the food’s benefit.

Modernist or molecular cuisine is not just about the powders or preservatives. The cooking methods, many of which include modern technology, are also a part of the innovation in food. The sous vide technique includes packaging the food in a Cryovac or vacuum-sealed plastic. Though chefs use high technology with a circulator, these are not necessary. It can be done with a ziplock bag in a microwave. Though these foods resemble packaged supermarket food that generally have a bad reputation, due to the ingredients and health risks associated with it, not all sous vide food is bad. Using the microwave is also not by definition bad. It allows quick cooking, which in the example provided by Michael Voltaggio in his YouTube video is a healthier alternative to cooking carrots or vegetables than a pot of boiling water. It keeps the nutrients in the package and does not let them out and leech them into the cooking liquid (Voltaggio brothers 2011). How good the food is dependent on what is placed in the package. The whole carrots in the microwaved package used by Michael Voltaggio will keep the natural sugars and nutrients in, thus making it a

healthy alternative to food (Voltaggio brothers 2011). This technique can be used with any ingredients and will keep the shape and the integrity of the food, as well as the nutrition. It is less harsh on the food item through its preparation and is, in many cases, a better alternative to cooking. It also creates a more consistent food product, one that is hard to mess up (Dickerman 2005).

Progressive or Modern Cuisine

Many do not believe it is ethical to label the chefs as molecular gastronomists. The scientists and culinologists argue the molecular gastronomists are the people who spend the time discovering and creating the products themselves (Zemser 2010) and transmitting the knowledge of the molecular reactions (This 2005). Others believe that calling chefs molecular gastronomists makes people believe that their food is a gimmick and that it is always attached to some sort of scientific creation. Though many of the creations of the chefs include ingredients or cooking methods that are innovative and scientific, there are other dishes and parts of creations that are straightforward interpretations of good food and traditional food preparations. For these reasons, the term “modernist cuisine” is more appropriate to the style of cooking of chefs like Grant Achatz, Wylie Dufresne, and Thomas Keller, just to name a few (Arnold 2009).

As many chefs began to imitate those who pioneered the food transformation, many bad copies arose. These were chefs who did not really understand the processes and also did not know how to blend them into traditional cooking techniques. However, they saw the difference in price range and fame that was brought to these pioneers. For that reason, they began to label themselves as molecular gastronomists and raised their food prices and became more well known (Melonas 2009).

There are many chefs who do not only focus on the innovation but also on the tradition of preparing good food. Some of them prefer the new term progressive or modernist cuisine. This has also proved less intimidating to the public (Melonas

2009). Many chefs dislike the modernist or progressive label as well and argue that they are still chefs; they focus on creating good food. Using different cooking techniques does not renounce the fact that they are preparing food for the public and they just want to be known as chefs (Melonas 2009).

Marketing Molecular Gastronomy

Chefs create, but do not teach; calling chefs molecular gastronomists is not appropriate (This 2005). Many chefs use the term to market themselves as innovators; this is also a tool to communicate to others that their menus feature modern or progressive cuisine. Using the term molecular gastronomy for these innovative creations is unethical; it is a misrepresentation of the term because molecular gastronomy is the science itself, not the cuisine (Koppmann 2009).

The Italian Department of Health banned the “powders” used within molecular gastronomy on a temporary basis. Their original claim is that these elements are not good for people’s health. Many chefs, such as Wylie Dufresne and Jose Andres, believe the Italian government is making an unethical choice, using this as a marketing tool to discourage people from being interested in and fall in love with the trend. After all, the Italians did not ban these ingredients from processed foods sold outside restaurants in markets and other areas. This temporary ban was put into effect for the period of only 1 year as a trial. Soon after the ban, the Italian Minister of Agriculture promoted the introduction of a new McDonalds burger, which led many chefs and molecular gastronomists to believe that it is the tradition of the classical Italian cuisine that they are looking to preserve and not that the ingredients are harmful for the health.

Journalists began to use “molecular gastronomy” to write about the trends of innovative cuisine. Not only is the term not properly used with chefs, but most of the better-known chefs labeled with it (Grant Achatz, Wylie Dufresne, and Ferran Adria, among others) who use innovative techniques also dislike the term (Arnold 2009). What has become known as molecular gastronomy is a

new idea, dish, or technique with high-technology equipment. However, at this point, chefs and pastry chefs of some of the most well-known restaurants in New York City, and in the world, use techniques and ingredients classified by journalists as “molecular,” but not all of them, such as Johnny Iuzzini, have been labeled as molecular gastronomists. The use of technology and avant-garde or innovative ingredients should not be labeled “molecular.” Giving it that title not only is a misrepresentation of what molecular gastronomy really is but also suggests that anything related to high technology or innovation automatically becomes a fad (Arnold 2009).

Using the label molecular gastronomy for all of the chefs using high technology or new ingredients begins to classify all of the chefs under the same category. Categorizing people with such different styles and approaches to food and restaurants is unethical. It is merging all of them together, as if they all had the same methods and personality. It creates an expectation to consumers that all of the restaurants and foods will be similar in style and have the same approach, since they all have the same label. This could not be further from the truth (Arnold 2009).

Summary

Molecular gastronomy is a field of study that looks at the chemical and physical changes foods undergo throughout the process of their manipulation. Due to many modern techniques, the term has taken another connotation. There are many ethical concerns with the field. Some of them have to do with the use of the term itself for food producers. Others have to do with the use of ingredients that in other food products seem to arise questions of health in consumers. This entry looks at the history, the evolution of the term, and the use within modern food preparations.

Introduction

Michel de Montaigne was among the most important Renaissance thinkers, the greatest advocate of skepticism, and the virtual inventor of the modern essay as a literary genre. After serving as mayor of Bordeaux, late in life (1571) he shut himself up in an “ivory tower” not to escape from the world but to contemplate humanity from an objective distance. Trusting that any true knowledge, as opposed to received wisdom, begins with a skeptical willingness to suspend all preformed assumptions, he dared to ask “Que sçay-je?” or “what do I know?”

The only logical place to begin is with self-examination, which itself has a long philosophical pedigree. The idea of “know thyself” (γνῶθι σεαυτόν) was associated by Plato with Socrates but is probably much older. Montaigne’s intellectual sojourn led to the composition of the essays in 1580. These as well as his travel journal contain numerous references to food, his own experiences, preferences, and bodily functions, which is only to be expected since he critically examines every aspect of himself. Montaigne’s writings present numerous ethical issues regarding food, most importantly how and what people should eat,

whom people should trust as authorities in matters of health and gastronomy, and ultimately how people should consider those with customs different from their own.

Book III Essay 13 *On Experience* focuses largely on Montaigne’s own eating habits. As the title of the essay suggests, experience is the best guide in determining food choices and dining customs. This implies that medical professionals cannot always be trusted, partly because they disagree so much among themselves, but also because their opinions are drawn from authoritative texts rather than from direct personal experience. Every individual is the best authority regarding his or her own body. Although the dietary precepts of the Renaissance are now wholly outdated, the modern reader can empathize with Montaigne’s comments, especially given familiarity with so many competing diets, fads, and foods marketed with explicit health claims. Today people are faced with the same dilemma: to trust expert medical advice, often proffered in the interest of profit, or follow one’s own bodily experience and taste preferences? Montaigne’s advice is generally to remain skeptical when it comes to food advice and choose a diet and mode of life that best suit one’s own body, ingrained habits, and customs, as learned over time.

This particular essay would today be called an autoethnography. By relating his own personal habits in regard to food, Montaigne attempts to communicate something essential about his character. In humoral medicine, the reigning medical orthodoxy of his time, a person’s taste preferences and habits and ultimately “complexion” were thought to be an indication of personality type and inner psychology. Thus choleric people are angry, melancholics depressed, phlegmatics slothful, and sanguine people cheerful and optimistic. Montaigne doesn’t actually classify himself using this scheme, which may be an indication that he was skeptical about the entire system. Nonetheless, food preferences do reveal something about personality and character and are used to communicate identity, which Montaigne seems to instinctively understand. Montaigne confesses to eating too fast and even biting his fingers in the process. Keep in mind that forks were still considered strange and effeminate and King Henry III was scandalized for using one in

a satire called the Isle of Hermaphrodites (Artus 1605). By admitting this, Montaigne reveals that he is generally impatient and voracious. His eating habits likewise reflect his intellectual capabilities; he similarly devours topics, fixating on one then moving quickly to another, though often coming back to savor familiar themes.

But his food preferences also carry culturally and socially constructed meanings specific to his own time and place. His preference for salt beef, for example, would have immediately signaled to his readers that his tastes and affinities are not with aristocrats who preferred wild fowl and delicate white-colored dishes, but with the bourgeois and even working classes. The labor undertaken by these classes was believed to give them strong stomachs able to digest coarse foods like beef. He also preferred undercooked meats and game hung to the point of becoming slightly rank. These preferences not only ran counter to dietary recommendations but importantly they show that he is not fastidious, has no squeamishness about food, and follows his taste buds rather than fashion.

More importantly Montaigne admits to a fondness, even preference, for fish, which was normally seen as a privation during Lent. “I am very fond of fish: for me lean days are fat and fast days are feasts. Besides I believe that, as some people say, fish is easier to digest than meat.” This was not the standard physicians’ advice, but quite the opposite. Once again Montaigne trusts his own body’s evidence over prevailing opinion. Moreover, the original purpose of Lent as a form of penitence is subverted, since he enjoys fish immensely and feels no need to find a suitable ascetic substitute, which may signal his skeptical attitude toward the entire institution of fasting. In any case, he admits that his tastes are unusual, and unlike everyone else, he hardly suffers during Lent. Contrast this with the situation of Erasmus, another great Renaissance figure, who couldn’t stand fish, purchased an official dispensation, and was embarrassed when people went out of their way to make special dishes for him. Montaigne, to say the very least, is much less fastidious.

Montaigne was also skeptical of medical authorities on the topic of diet. The dominant system of humoral physiology posited that each person was

born with a certain complexion and the foods they eat should be of an opposite quality to maintain a humoral balance. Therefore a choleric (hot and dry) person should eat cold and moistening foods and phlegmatic hot and dry – or spicy – foods. The basic logic is allopathic. By the latter sixteenth century, this entire system, which stretches back to classical antiquity, began to be questioned, since a barrage of conflicting dietary advice generally confused readers, much like today. There were literally dozens of dietary manuals published in this era, and Montaigne seems to have appreciated their effect on readers who followed the latest fad: failure. “If your doctor does not think it good for you to sleep, to take wine, or some particular meat, do not worry; I will find you another who will disagree with him.”

This attitude toward physicians and dietary dogma was not unique to Montaigne, but rather indicative of a gradual breakdown of Galenic orthodoxy in the latter sixteenth century, which led many writers to examine the book of nature directly rather than the medical classics. In fact, the autobiography of the great mathematician and physician Girolamo Cardano, roughly contemporaneous with Montaigne, strikes many of the same notes. In chapter 8 on *Manner of Life*, he too describes what he normally eats each day and even his favorites like pot-roasted veal (Cardano 2002). Like Montaigne, he enjoys fish and fruits like peaches, despite the dire warnings of physicians. The best practices learned through experience are here too the greatest authority.

Among the Renaissance, dietary fads none was more popular than the *sober diet* recommending strict reduction of intake and general abstinence. Spread by Alvise Cornaro in mid-sixteenth century, its author was the original “before and after” example of a life nearly wrecked by riotous living but then miraculously cured by strict abstinence (Cornaro 1996). Most importantly Cornaro was given a wide range of differing advice, which in the end he ignored, following the messages of his own body instead and living to extreme old age in perfect health. Exactly like Montaigne, his own body told him what to do; it was merely a matter of trusting oneself. Actually, it is likely that

Cornaro was a diabetic since he found solely through trial and error that sweets would make him sick and that severely limiting his intake kept his blood sugar level stable. Naturally this regimen would not work for everyone. Montaigne also understood that his own experience could not serve to guide his readers – and that abstinence would not work for everyone. Having suffered himself from kidney stones, Montaigne appreciated the fate of a member of the medical faculty who resorted to extreme abstinence to combat his disease and died, by drying up his kidneys, according to his physicians, a story he relates in the same essay. That is, each person should refer to his own experience in self-diagnosis and therapy and one individual's personal judgment, such as Cornaro's, could not be taken as universal advice. Ironically it was, even though Cornaro himself insisted on trusting himself.

The other details of the essay *On Experience* may strike readers as quirky or coincidental, but they actually reveal that Montaigne was thinking about much broader philosophical questions in gastronomy and aesthetics in general. For example, when he mentions that his father hated sauces but he loves them all, he is indirectly wondering why taste is not inherited like physical attributes. He also wonders how it is that taste changes over time and with age, sometimes randomly. Radishes once agreed with him, then they didn't and later they did again. Purely aesthetic questions also seem to fascinate him. Montaigne discusses how throughout his life he has often skipped a meal, merely so he will appreciate the next meal more, not like Epicurus who wanted to accustom himself to little food and not depend on luxuries. Interestingly, Montaigne seems to be among the few food writers since then who really understands Epicurus.

Montaigne also notes how eating too much dulls both his mind and body and in particular how difficult sex is after a big meal. Like a good anthropologist, he also notes that the pleasure of a meal hardly consists in the food itself. The company is far more important. "There is no dish so sweet to me, and no sauce so appetizing, as those derived from the company." Montaigne was also a keen observer of the customs of other peoples and

in particular how their bodies become habituated to local practices. The most obvious one is the custom of diluting wine with water, which was the typical custom not only in the great wine capital of Bordeaux but in most of Europe. But he knows Germans drink their wine straight, and since this custom serves them best, they should continue to follow it, regardless of what physicians claim.

Montaigne's opportunity to observe the customs of other countries was made possible in particular by one long trip. In 1580–1581, Montaigne took a 17-month journey through Germany, Switzerland, and Italy, mostly visiting various mineral baths to search for a cure for his kidney stones. The trip was recorded in his travel journal, the manuscript of which was first discovered in 1772. It recounts many of unusual customs he encountered in these places and again relates the same theme of objectivity when discussing the wide variety of human habits.

The most celebrated passage regarding food occurs while in Rome, when Montaigne met the *Maitre d'* of Cardinal Carafa who offered a discourse on the "science de guele" with a magisterial countenance as if he were discoursing on a fine point of theology. The encounter is described in Book 1 chapter 51 *On the Vanity of Words* as an example of the incongruity of grandiose verbiage to describe the proper seasons for eating hot and cold salads, how sauces should be ordered, and so forth. Food scholars cite the episode as evidence of the importance of gastronomy to Italians in the sixteenth century, but explain no further the details of the discourse.

First, the character Montaigne met closely matches a real person who was in Rome at the time. He may very well have met the famous banquet manager Cesare Evitascandalo, who composed the *Il Maestro di Casa* (i.e., *Maitre d'*) in Rome in 1585, which was subsequently published in 1598 (Evitascandalo 1598). The book is indeed about various officers of the household employed by cardinals, including the *trinciante* or carver, whom Montaigne mentions in the Latin quote on carving hares and chickens. Evitascandalo even mentions a Cardinal Carafa in a passage about table settings. This was Antonio Carafa, rather than the earlier and more

famous cardinal Giovanni Pietro Carafa who became Pope Paul IV and died in 1555.

In Montaigne's journal entry, the *Maitre d'* discusses the qualities and effects of various ingredients. This was standard subject matter in the genre of Scalo (banquet management) literature, as was garnishing and decorating food to render it more pleasant to the eye. He distinguishes between salads that should be served cold and those that are best hot according to season and how to recognize the difference between an appetite at the start of a meal and how to revitalize or pique the appetite after two or three courses. Obviously these are gastronomic questions which no longer concern us today, yet were of great importance to cooks and banquet managers of the past. Although there are some universal truths about human nutrition, clearly Renaissance people had a very different understanding of what was occurring in their bodies, and a need to stimulate the appetite mid-meal appears to have been a genuine concern.

Another phrase Montaigne relates that would confuse a modern audience is the "*La police des sauces*" not merely ordering but controlling and regulating the use of sauces. There are two senses in which one might interpret this phrase, either which sauce goes best with which ingredient from a gastronomic perspective or which serves as a corrective to the potentially harmful qualities of the dish.

Passing through Switzerland, Montaigne noted many of the common customs of the people, for example, that they are good cooks, of fish especially, implying that they cared more about what they ate than housekeeping, which he found lacking. Their table service was also very different from what Montaigne was accustomed to. They never mixed water with their wine, which he assumed stemmed from the weakness of the wine. He also remarks about how they serve only two or three types of meat, sliced and presented on the same dish. In France many dishes would have appeared at once on separate platters, known as *service à la Française*, and dishes would have been replenished as they were depleted. In Switzerland new dishes never appeared until those on the table were entirely consumed.

Montaigne relates these customs generally without criticism, in keeping with his skeptical attitude toward any universal pronouncement about what is right or wrong. People develop customs which suit them and though they seem strange, they make sense in context. Montaigne marvels, for example, how the Swiss regale the lowly crayfish, considering it a delicacy, which is entirely appropriate given their pristine source.

At Lindau in Bavaria, he waxes rhapsodic about the quality of the food he is served. There is soup made of quince, rice dishes, excellent fish, and the most tender meat he had ever eaten, cooked with plums, apples, and pears. He sorely regretted not taking along a cook who could have learned these recipes and taken them back to France. A good sense of the food he ate here can be found in the cookbook of Anna Wecker, published in Amberg in 1597. There are many recipes for cooking apples with meat, of exactly the type Montaigne enjoyed. When in Tirol he notices that people eat fish and meat together, but that meat is never served on fasting days, adhering strictly to Catholic ban on meat during Lent. Apart from curiosity and the urge to observe, Montaigne mentions these differences in gastronomic preferences and regional customs to point out that people should never be absolutely certain of the correctness of their own habits.

Of course the ultimate discussion of relativism when it comes to food is about cannibalism, in one of Montaigne's most celebrated essays. Here he describes Native Americans, drawn largely from contemporary accounts and perhaps from an individual he met in Rouen, brought from what is today Brazil. Montaigne describes their ordinary eating habits: "Their drink is made of a certain root, and is of the color of our claret, and they never drink it but lukewarm. It will not keep above 2 or 3 days; it has a somewhat sharp, brisk taste, is nothing heady, but very comfortable to the stomach; laxative to strangers, but a very pleasant beverage to such as are accustomed to it. They make use, instead of bread, of a certain white compound, like coriander seeds; I have tasted of it; the taste is sweet and a little flat."

Eventually he describes their eating of human flesh. The essay is of course not advocating

toleration of cannibalism, but rather objectivity, that Europeans should not be so quick to call a practice barbaric when they commit equally horrible acts themselves. Here he was thinking of the terrors of the civil wars over religion which rent France apart in this century, and in which people were tortured and burned while alive, certainly worse than eating a person after death.

While not generally acknowledged to be a writer especially concerned with food or the ethics of food topics, Montaigne's writings reveal that he was continually actively engaged with questions about food, many of which still concern us deeply today.

Summary

Montaigne was a skeptical Renaissance thinker who revealed his own eating habits and those of others as a way to gain insight into individual personality, national character, as well as universal patterns of gastronomic behavior. He also discusses numerous ethical concerns of his own day: whether physician's advice should be trusted over one's own experience, whether people should stick to their native habits, and whether we should be tolerant of differences among peoples.

Multifunctional Agriculture

Stefan Mann

Agroscope, Institute for Sustainability Sciences,
Ettenhausen, Switzerland

Synonyms

Externalities; Fringe-benefits and heterodox economics; Utilitarianism

Introduction

The innovative, indeed provocative nature of the concept of multifunctional agriculture can only be understood fully by thinking back to agriculture's role in twentieth-century society during the Cold War era, which was simply to provide food for a growing world population. Within this line of thought, two different scenarios were posited: whereas Neo-Malthusians seriously questioned the ability of farmers to cope with the rapid increase in population, particularly in southern Asia (Commander 1986), others, adopting a more western perspective, observed the remarkable productivity gains in the farming sector and concluded that only half of the land would have to be farmed (Kuhlmann 1986). In any case, agriculture was merely the location of a production function in which labor, fertilizer, and other factors were to be transformed into wheat, rice, and beef. Organic agriculture and other attempts at environmentally sensitive farming were on the

very fringes of society, viewed highly skeptically by initial government investigations (Paster 1980), their products largely absent from supermarket shelves.

By that time, the term “multifunctionality” had already been coined: in a book by a German forestry-policy researcher (Dietrich 1953), the existence of jointness and externalities was for the first time perceived as being a constituent element of an economic sector. With the description of this notion as the “multifunctionality of forests,” a new concept entered economics. At the time, however, hardly anybody took any notice of the phrase. Much later, the concept began to be revived for political discourse, with the result that the concept was still described as follows 20 years ago:

In his Vision 2020, Mr. Kienle [Secretary-General of the German Farmers' Union] talks about ‘multifunctional’ agriculture. He defines this as agriculture in one's own country which produces food and fibre, but which is also perceived as indispensable owing to its environmental tasks and societal functions. (Thiede 1992, p. 299; translation by S.M.)

Over the last 20 years, the theoretical concept of multifunctionality has undergone significant development. It is important to note, however, that the main impetus for this development has come from the policy process rather than from academia, most notably for the purpose of defending EU protectionism in international trade negotiations (Potter and Burney 2002). The next section of this paper sets out the main arguments of key international actors in the agricultural sphere. The final section then describes the potential impact of the concept of multifunctionality on agricultural ethics.

Why Is Agriculture Multifunctional?

While the Commission of the European Union has elaborated the notion of the multifunctionality of agriculture as a mainly normative concept (EEAC 2000), there is certainly no other organization which has contributed more decisively to challenging and elaborating the concept of

multifunctionality from a theoretical viewpoint than the Agricultural Division of the OECD. The latter's analysis stands as a mainly environmental economic approach that essentially describes the multifunctionality concept as a tool for the appreciation and internalization of external effects. Changing shortages lead both to new functions of agriculture and to the creation of new markets for commodities and non-commodity outputs alike, with the ensuing problem of failing markets for some of these outputs.

A wide variety of jointly produced, largely mutually inseparable agricultural non-commodity outputs such as soil preservation, land degradation, landscape scenery, tradition, and employment were identified, classified, and defined by each participating country (OECD 2001a). The OECD secretariat formulated its stance, however, as follows: "The key elements of multifunctionality are: (i) the existence of multiple commodity and non-commodity outputs that are jointly produced by agriculture; and (ii) the fact that some of the non-commodity outputs exhibit the characteristic of externalities or public goods, with the result that markets for these goods do not exist or function poorly" (OECD 2001b, p. 8). It is becoming obvious that the OECD definition of multifunctionality is strongly output related: employment, for example, which is identified by the OECD as a non-commodity output, is also a necessary input in the production process.

Multiple commodity and non-commodity outputs are therefore the first key element making a production process multifunctional (OECD 2001b). With sheep production, for example, a wide variety of commodities such as meat, wool, and milk are produced as part of the process of sheep-rearing, rendering this activity multifunctional without even bearing in mind the resultant non-commodity outputs or rather externalities. The sheep-production process is thus characterized by a number of outputs (i.e., commodities and externalities) that are interconnected. Generalizing this notion, all production processes allowing for all weight and energy fluxes are characterized by some sort of joint production (Baumgärtner and Schiller 2001). The radical view is that joint production is in fact a

necessary characteristic of all production processes (Baumgärtner 2000). It would also appear necessary to extend the definition of production to nontechnical processes.

An even more important aspect is the "jointness" that exists between commodities and externalities. The relationship between commodities and externalities within the production process is becoming increasingly important, especially where the concept of traditional agriculture has changed and the relevance of the resulting by-products is therefore growing. A case in point, many European farmers are paid by the government to keep grassland open with the aim of producing the externality "biodiversity." The process of keeping grassland open is mainly achieved by husbandry and thus by producing commodities. Were the farmer to increase livestock numbers, thereby increasing commodity production, the production of the externality "biodiversity" would arguably also increase to a certain extent. Thus, a complementary "jointness" exists between the externality of biodiversity and the commodity (wool, milk, or meat). Beyond a certain point, however, the increase in livestock numbers within a limited space would adversely affect biodiversity, owing, e.g., to the higher level of organic pollutants from the animals (competing jointness). Moreover, a backward-bending effect of the production curve is also conceivable. The larger number of animals would have a negative impact on the original population, due to a shortage of space and fodder alike.

Mann and Wüstemann (2008) have suggested that in addition to physical products and technological externalities, the range of outputs of a production process also comprises psychological, social, and human capital externalities. With such a broad interpretation of the concept of multifunctionality, it is obvious that this term not only applies to the agricultural sector but would also be a powerful concept, for example, in the context of the provision of cultural services. Moreover, as Rørstad et al. (2007) have pointed out, it is not always useful to replace general support measures with programs targeting individual externalities. The transaction costs necessary for the administration of many small government measures may

easily exceed the welfare gains from a more targeted policy. This applies particularly if some of the externalities are not amenable to a reasonable and realistic monetary evaluation.

Implications for the Ethics of Food Production

For a long time, discussion about ethically sound strategies of agriculture took place mainly in two different subgroups. Scholars with a deontological orientation emphasized the rights of different groups in agriculture. They described the support to poor peasants as an appropriate tool of social policy (Granberg 1999), focused attention on animal rights (Benton 1993), and mused about the need to preserve biodiversity (Zunino and Barbero 1993). Utilitarians, however, usually approached agricultural policy from a different angle: In applying public choice theory, they acknowledged the strong representation of the farmers' union and considered subsidies for farmers as an outcome of political pressure (Balisacan and Roumasset 1987). At the same time, simple welfare-economics models convinced them that social utility could easily be maximized by leaving the agricultural sector to market forces (Anderson 1992).

The paradigm of multifunctionality has shown that utilitarians can easily reach similar conclusions to those of deontologists. If a given agricultural production process brings about a wide range of externalities that are relevant for personal utility, this indicates that the absence of government involvement will probably not lead to utility maximization. This allows the justification of sometimes massive policy interventions from a utilitarian perspective.

Take animal welfare as a case in point. Surveys have repeatedly shown that a number of populations are greatly concerned about farm-animal welfare (Bennett and Blaney 2007; Böbner and Vogel 2007). Chickens in cages or pigs on fully slatted floors appear to cause massive negative psychological externalities. Under these conditions, utilitarians may arrive at the same policy recommendations as deontologists, who claim

that raising animals under such low-welfare conditions should be prohibited.

The multifunctional agriculture paradigm does not answer all questions raised concerning the formulation of appropriate agricultural policy. It does, however, clarify the position of those who are convinced that farming is much more than just calorie production.

Summary

Multifunctional agriculture describes farming systems with numerous positive externalities which only partly can be reasonably put into monetary values. The notion that utility can be maximized by broadly supporting agriculture brings the utilitarian approach closer to traditional rights-based arguments.

Multifunctionality of Agriculture and International Trade

Introduction

As the guarantor of our subsistence, “agriculture is a security matter” (PISANI 2004). It is the oldest political issue and probably one of the most worrying in the years to come.

In the current framework of the World Trade Organization (WTO) agricultural trade negotiations, the aim of reducing, or even suppressing, the impossibly high custom tariffs of the 1980s has not been achieved and seems in fact to have reached its limits. These have been highlighted by the deadlocked Doha Round negotiations and the endless debates and disputes inherent to these talks. They might even point to the culmination of a system. The tariffs that have been immune to past efforts to reduce them now represent the core of national protective barriers, and the political cost of tariff reductions seems today way too high compared to their potential for economic gain. The July 2008 dispute between India and the United States, concerning the definition of the precise moment when a special safeguard mechanism can be triggered in case of falling agricultural prices or of a drastic increase of imports, is an example of the difficulties of reaching agreement in the current framework for agricultural trade negotiations.

Misunderstandings on agricultural policy are first and foremost cultural and political and are therefore extremely difficult to overcome. The

Multifunctional Farming Strategy

► [Permaculture](#)

scenario of a complete liberalization of agriculture does not seem particularly relevant at the present time, and even though liberalization of trade in agricultural products is set in the WTO's agenda, that agenda is currently stalled and even be frightening to some. Consequently, instead of focusing on the "for-or-against" debate on agricultural free trade, should we not question the need to maintain agricultural policies that ensure food security, preserve the rural fabric, and encourage countryside planning as well as environmentally sustainable modes of production?

Agriculture is in fact much more than simply an economic activity. In developing countries, it employs the vast majority of the population, and it is also a particular type of lifestyle that answers a fundamental human need: hunger. Agriculture also fulfills many different functions: not only does it produce food, it creates jobs and boosts the rural economy. In addition, it is a crucial element of environmental management: farmers play a very important part as guardians and protectors of the land and living environments.

Given the lack of consensus on agricultural trade, the WTO has not managed to establish a negotiating framework that transcends the traditional issues of tariffs and subsidies, and this is probably the reason explaining the current deadlock in trade talks. In order for the WTO to be in a better position to address the concerns of its members and civil society on representativeness and legitimacy issues, it should integrate global sustainable development aims much more explicitly in its agenda.

Therefore, the idea would be to better take into consideration the social and environmental aspects of agriculture within trade negotiations in order to overcome the divisions that have stymied progress on the Doha Development Agenda. In fact, Article 20 (c) of the Uruguay Round Agreement on Agriculture as well as the November 2001 Doha Ministerial Declaration require that "non-trade concerns" be taken into account in the WTO negotiations (WTO 2001b). These social and environmental considerations of agricultural international law (food security, land access, and environmental concerns) refer, in fact, to the concept of the multifunctionality of agriculture.

The multifunctionality of agriculture is based on the concept of externalities (side or external effects) and public goods. More specifically, farmers may produce goods or services that possess the characteristics of externalities of productive activity affecting the well-being of citizens. Externalities can be positive or negative. They are not or insufficiently taken into account by the market.

Positive externalities refer to situations where citizens benefit from the action of the farmer without having to pay anything. Enhancement of the landscape and protection of biodiversity are examples of positive externalities generated by agriculture. However, for the farmer, the production of these goods or services may involve costs that are not internalized in the price of his or her products. We then say that there is market failure.

There are also negative externalities of agricultural production such as soil erosion, sedimentation, or pollution. If the farmer does not assume the costs that may be involved, it is the general public that may experience a worsening of its current and future well-being.

Public intervention may be necessary to remunerate the positive externalities of agriculture, corresponding to the expectations of society, or to compensate for and reduce negative externalities. To recognize the multifunctional character of agriculture is to recognize the positive externalities of agriculture.

Legal Recognition of the Multifunctionality of Agriculture

Since the Club of Rome called for, in 1968, a "zero-growth" approach in order to offset the increasing scarcity of natural resources, concerns about the environment as well as about natural resources and their renewability have multiplied in all relevant international fora. International law recognizes, and has done so for many years now, the concept of a multifunctional agriculture. This concept made its first appearance in the Agenda 21 adopted by the UN in Rio in June 1992 during the "Earth Summit." The Quebec Declaration, adopted in 1995 during the Food and Agricultural

Organization's (FAO) 50th anniversary conference, as well as the 1998 OECD (Organization for Economic Co-operation and Development) ministerial conference also explicitly refers to it.

The introduction of the notion of multifunctionality in agricultural trade negotiations originates in the final agreement of the Uruguay Round which recognizes the importance of taking into account the "non-trade considerations" specific to each state in the process of liberalization. During this round, the European Union (EU), Japan, Norway, and Switzerland put forward the possible consequences of rapid and deep agricultural liberalization for the environment, national food safety, and the risks of destabilization of the agricultural sector. Joined by Korea and Mauritius, these countries constitute the group known as the "Friends of Multifunctionality" at the WTO.

Thanks to this group of countries, these concerns are included in the Agreement on Agriculture and referred to as "non-trade concerns": "commitments under the reform program should be made in an equitable way among all Members, having regard to non-trade concerns, including food security and the need to protect the environment" (paragraph six of the Agreement on Agriculture's preamble). According to Article 20 (c), these concerns should be taken into account in the agricultural trade talks that started on January 1, 2000, in accordance with the agenda set in the agreement: "recognizing that the long-term objective of substantial progressive reductions in support and protection resulting in fundamental reform is an ongoing process, Members agree that negotiations for continuing the process will be initiated 1 year before the end of the implementation period, taking into account (...) non-trade concerns" (Article 20, Continuation of the reform process).

During the conference on non-trade concerns in agriculture held in July 2000 in Ullensvang, Norway, a number of WTO members expressed their openness toward the issue of non-trade concerns in agriculture, particularly so in the rural development, food security, and environmental protection sectors. In a joint note on non-trade concerns, submitted to the Special Session of the WTO committee on agriculture in November

2000, 27 member countries declared that "Every country has the right, in accordance with mutually agreed rules, to address non-trade concerns, such as strengthening the socio-economic viability and development of rural areas, food security and environmental protection, and promoting the coexistence of various types of agriculture."

The concept of the multifunctionality of agriculture quickly emerged as a controversial concept. Indeed, this concept has sometimes been interpreted as having implications for trade and protectionism, some countries justifying further subsidies based on this concept. Following the controversy caused by this debate, the Organization for Economic Co-operation and Development (OECD) tried to formulate an analytical framework for the concept of "multifunctional agriculture" based on the following points (OECD 2001):

- the existence of multiple commodity and non-commodity outputs that are jointly produced by agriculture;
- the fact that some of the non-commodity outputs exhibit the characteristics of externalities or public goods, with the result that markets for these goods do not exist or function poorly.

The OECD also formulates two possible approaches to the analysis of multifunctionality, interpreting it either as a characteristic or as a goal:

- The positive approach consists in interpreting multifunctionality as the characteristic of an economic activity. The particular characteristic that makes an economic activity multifunctional is its multiple, interconnected outputs or effects. These outputs can be positive or negative, intended or unintended, complementary or conflicting, and reinforcing or offsetting. Some of the outputs are valued in existing markets, whereas others may elude the market mechanism. Multifunctionality, interpreted in this way, is not specific to agriculture; it is a property of many economic activities. There are numerous ways in which economic activities can be multifunctional. A certain activity may be multifunctional or not, but there is no implicit notion that it should be multifunctional.

- The normative approach defines multifunctionality in terms of the multiple roles assigned to agriculture. In this view, agriculture as an activity is entrusted with fulfilling certain functions in society. Consequently, multifunctionality is not merely a characteristic of the production process, but it takes on a value in itself. Maintaining a multifunctional activity or making an activity “more” multifunctional can become a policy objective.

The positive approach, chosen by the OECD, leads to purely economic reasoning consisting in identifying goods and services in terms of supply and demand equilibrium models. This is, in terms of public policy, an extremely reductive way of seeing things compared to the normative approach. The European Union (European Commission 1999) and the FAO (2004), on the other hand, have chosen the second approach. As highlighted in the European Commission’s report, agriculture is multifunctional because it is not simply limited to the production of agricultural commodities; it also has to guarantee food safety, protect the environment, and sustain rural employment. The agricultural sector’s unique features are put forward in order to explain the specific role of agriculture in society: agricultural production as a nature-bound process, facing inelastic demand, situated in space, as well as having particular strategic and cultural characteristics. This approach is a more cultural- and identity-based approach, superimposed on a purely market-based approach.

The Stance of Advocates of Multifunctionality

Supporters of multifunctionality consider that agriculture fulfills several functions, in addition to the production of food and agricultural goods. These functions derive from the specific nature of the agricultural sector as well as from the sociological, economic, historic, and cultural context in which agriculture is situated. These supporters recognize agriculture’s role in environmental and landscape protection as well as its importance in rural development. They equate the multiple roles of agriculture to the delivery of goods and services of general interest. Due to their public character, these goods and services cannot be produced by

the market in sufficient quantities to meet social demand and, above all, cannot be obtained by any means other than agricultural activity.

The potential for agriculture to yield environmental services is now widely recognized among the OECD countries. For example, it is stated in an OECD document that “the provision of environmental benefits and amenities is increasingly seen as an element of the multifunctionality of the agricultural sector.” The word “amenities” is important because it differentiates the concerns of industrialized countries from those of developing countries, with those of the former focusing primarily on protecting agricultural landscapes and those of the latter focusing on the resource-protecting services – prevention of soil erosion and watershed protection, for example – without which food security may be threatened.

Developed country advocates of multifunctionality (EU, Japan, Norway) thus call for a review or an enlargement of the criteria defining the measures that are exempt from the reduction commitments made under the WTO Agriculture Agreement. Norway, for example, considers that the support granted to agricultural production destined for the domestic market should be subjected to less stringent reduction commitments than those for traded commodities. Korea wishes to see new measures, especially compensatory supports for the multifunctionality of agriculture, exempted from reduction commitments. Korean delegates are concerned about restrictions on “supports for maintaining domestic production capacity of staple crops for food security purposes,” as well as support measures designed to strengthen producers’ income safety nets, help small farm households, and boost agricultural and rural development in developing countries. Finally, Japan has called for an improvement of the criteria for green box designation (subsidy reduction exemptions for policies related to the environment) in order to be able to better take into account the public aspects of agricultural production.

The Arguments Against the Recognition of the Multifunctionality of Agriculture

The countries that have expressed the strongest reservations regarding multifunctionality are

those in the Cairns group (especially New Zealand, Australia, South Africa, and Argentina) as well as the United States. For representatives from these countries, the multifunctionality argument is more precisely described as the claim that agriculture generates positive externalities in addition to the primary output, food. Externalities, which can be both positive and negative, arise when the private costs and benefits of economic activities differ from the social benefits and costs of these activities. Economic agents are influenced by the private costs or benefits ignoring the social impacts. The costs of negative externalities are borne by society as a whole rather than the individual decision-maker, while the benefits of positive externalities are uncompensated.

From this perspective (essentially, the positive approach described above), multifunctionality is not specific to agriculture, as every economic activity inevitably generates externalities. Moreover, in this regard, national or domestic agricultural industries are not necessarily intended to guarantee food security and the viability of rural communities, especially in developed countries. Food security should rather be seen as a joint product or as an externality of trade rather than an outcome of national production. Diversification of supply sources constitutes a better strategy than the sole development of national supplies against the risk of supply shortages, the latter being subject to meteorological, phytosanitary, or sanitary uncertainties. Greater trade liberalization would contribute to the stabilization of global commodity prices, especially by eliminating the disruptive effects generated by states' trade and agricultural policies and by reducing climate risks. Similarly, the viability of rural communities is considered to be more closely related to other sectors or to the agrifoods sector as a whole rather than to the agricultural sector itself, considering particularly the declining importance of agriculture in industrialized countries in terms of jobs and contribution to rural income.

Opponents of multifunctionality suggest that every single country has legitimate non-trade concerns and objectives, but these remain subject to

“the long-term objective of substantial progressive reductions in support and protection, resulting in fundamental reform” of the agricultural sector (Article 20 of the Agreement on agriculture). Continuing the reform process is still the best way of boosting growth and development. According to these countries, multifunctionality is being used as an excuse to maintain trade-distorting agricultural support, as increasing trade liberalization is not incompatible with pursuing the objectives related to multifunctionality.

The Divergent Views of Developing Countries

Given their heterogeneity, developing countries do not have a common position in agricultural talks.

The developing countries which are members of the Cairns group (they are all agricultural exporters) wish to see increased and accelerated agricultural trade liberalization and call for further opening of the domestic markets of partner countries to their products.

On the other hand, some developing countries have embraced the positions of the Friends of Multifunctionality (Barbados, Burundi, Cyprus, Estonia, Fiji, Latvia, Mauritius, Mongolia, Poland, Slovakia, the Czech Republic, Romania, Saint Lucia, Slovenia, Trinidad and Tobago). They argue that agriculture is a key sector in the pursuit of vital national objectives. With the Friends of Multifunctionality, these countries submitted a note to the WTO on non-trade concerns reflecting the achievements of the international conference held in July 2000 in Ullensvang, Norway (European Commission 2000).

Between these two extremely different positions is found a group of eleven countries that have proposed the creation of a development box (Cuba, Haiti, Honduras, Kenya, Nicaragua, Uganda, Pakistan, Salvador, Sri Lanka, Dominican Republic, and Zimbabwe). India also is favorable to a food security box. The suggested development box would group together a list of products to which domestic support or market access commitments would not be applicable. Just like the special safeguard clause, mostly available to and used by developed countries, it

would allow the implementation of a set of border protection mechanisms in the case of a drastic increase of low-cost imports endangering national production. Finally, it would include provisions aimed at facilitating access to developed countries' markets and would prohibit dumping. India, whose agricultural policy is traditionally quite close to that of the Friends of Multifunctionality, nonetheless denounces multifunctionality used as a way to justify high levels of protection. Its food security box aims at exempting intervention tools guaranteeing food security from liberalization commitments.

The Multifunctionality of Agriculture: A Guarantee for Its Sustainability

The agricultural question has once again become a geopolitical issue which will probably turn out to be increasingly complex given the demographic, environmental, and socioeconomic challenges of the twenty-first century. The current state of agriculture leads to a number of questions for the future, and for many of these, there is still no answer. The challenge will be to include the social and environmental aspects of agriculture in international negotiations in order to guarantee its sustainability. In 1931, Paul Valéry wrote in *Reflections on the World Today*: "And so begins the era of the finite world"... Something new must therefore begin. ...

The Agricultural and Food Challenges of the Twenty-First Century

Over the next four decades, agriculture will have to face multiple challenges. First of all, there will be nine billion inhabitants on Earth in 2050 (compared to the current seven billion). The planet will therefore need to produce more with fewer agricultural workers given increasing urbanization. By 2015, one in two people will live in cities and by 2050 two out of every three human beings will be city dwellers, which means concretely that there will be more consumers but fewer producers. Africa, for example, is thus expected to see its general population double

and its urban population triple by 2040. Moreover, each year, 30 million hectares of land are lost in the world due to urbanization and industrialization. Last but not least, not only is the agricultural population shrinking but it is also getting older, especially in developed countries. Indeed, in most developed countries, only three to six percent of farmers are less than 35 years old (EUROSTAT 2010) – two thirds are over 55 – and one can thus legitimately question the sustainability and the durability of agricultural activity in these countries.

According to the FAO (2011), agricultural production needs to be increased by more than two thirds by 2050 in order to be able to face these challenges. Yet, the growth of agricultural production is decreasing and, each year, 30 million hectares of land are lost because of the sprawl of cities and transport networks. Moreover, the use of petroleum-based inputs will have to be reduced and global pressures on water resources will have to be curbed.

Agriculture is thus now at a historic turning point. Not only will it have to meet the demographic challenge of a need for increased production and the environmental challenge of preserving ecosystems, but it will also have to work toward raising the living standards of agricultural producers as there will clearly be no agriculture without them. Guaranteeing farmers a decent income will be crucial for global food security. Agriculture has a cost and we should have enough foresight to pay its price.

The Relationship Between Agricultural Sustainability and Competitiveness

The sustainability of agriculture inevitably raises the issue of its competitiveness. In order to be sustainable, an activity must be competitive: there is therefore a clear link between these two elements in a competitive and globalized economy. Yet, in certain areas of poor countries and even in developed countries, agricultural sustainability is clearly challenged by its lack of competitiveness. The question is now to know how competitiveness should be defined in a sustainable economy.

The aim of sustainable development (UNGA 1987) is to set and implement viable models that reconcile the economic, social, and environmental aspects of human activities. These are the three “pillars” of sustainable development which need to be taken into account by governments but also by companies and individuals. The ultimate purpose of sustainable development is thus to find a coherent and viable long-term balance between these three pillars.

When discussing agriculture’s multifunctionality, one should not limit the debate on competitiveness exclusively to economic criteria. Indeed, this debate should include the environmental and social aspects of the issue just as it seems obvious to establish the environmental and social history of a product in its price and cost of production.

The Explicit Inclusion of Sustainable Development Global Aims in International Negotiations

Future agricultural trade negotiations should clearly identify non-trade concerns of agriculture such as social and environmental considerations. Given the challenges associated with sustainable development, the recognition of the multifunctionality of agriculture will visibly constitute the main driver for the evolution of agricultural policy toward environmental respect and the aim of food security.

This approach would in fact question the multilateral *modus operandi* based exclusively on free trade: instead of being solely in charge of promoting free trade, the WTO would be put in charge of organizing and rationalizing the necessary protections needed by states in order to offset the negative impacts of trade liberalization as well as of safeguarding the positive externalities of agriculture in the environmental and food security sectors. As a result, the WTO would stabilize the trading system and would reduce protectionist incentives without completely inhibiting them. The challenge is thus to find the proper balance and to elaborate neutral solutions in order for countries not to be accused of defending particular interests. This calls for a generic definition of the criteria and degrees of flexibility. This would

enable the defense of protection motivated by non-trade concerns such as food security, environmental protection, and social considerations of agriculture.

The Doha Agenda was set on the basis of a hypothesis of overproduction and of a fall in agricultural prices amplified by agricultural policies which would distort the commercial advantages of developed countries at the expense of developing countries. However, today the trend has been completely reversed. Now the issue is not the need to handle surpluses and the deflation of international prices but to deal instead with scarcity and tensions on the agricultural market. It is therefore essential to update WTO rules in order for them to meet these new challenges and to rebalance them to face the social and environmental concerns of the twenty-first century.

In order to address these non-trade concerns, it could be envisaged to:

- Reformulate article XX of the WTO in order for it to define in a precise and updated way its principles and to integrate more explicitly sustainable development objectives (food security, environmental concerns, multifunctionality of agriculture)
- Coordinate the WTO rules with those of other international organizations (FAO, UNCTAD, UNDP) in order to correct the deficiencies linked to its overspecialization

Conclusion

Is there a right to difference? This is in fact the crucial issue of the debate on the multifunctionality of agriculture as well as on non-trade concerns. This debate is contentious because of political and cultural misunderstandings that are hard to overcome and the fact that the general objective of trade liberalization is often difficult to reconcile with the necessity of maintaining agricultural policies which ensure food security, preserve the rural social fabric and land use planning, as well as encourage environmentally sound production patterns.

The WTO Dispute Settlement Body itself has increasingly been taking into account non-trade concerns. Through its interpretation of the Shrimp-Turtle case, for example, its Appellate Body permitted the adoption of unilateral measures for the protection of the environment (WTO, DSB 2001a). The Doha Declaration confirms this trend: “We recognize that under WTO rules no country should be prevented from taking measures for the protection of human, animal or plant life or health, or of the environment at the levels it considers appropriate” (WTO 2001b).

Arising from cultural, sociopolitical, and environmental factors, agricultural policies today express the aspirations of consumers for certain types of consumption patterns, the preferences for a certain type of production, and, more generally, the relationship between society and its diet and agriculture. The tensions arising from the hormone-treated beef and GMO cases illustrate perfectly Europe’s and North America’s different perceptions on these issues. But however contentious these North/North tensions can be, the North/South fracture is even more radical as the incorporation of sanitary, environmental, and social requirements in agricultural policies reflects the level of economic development and social demands while also being an obstacle to the import of Southern agricultural products to the developed countries’ markets. According to Pascal Lamy “the issue of collective preferences in trade conceals a structural divide between the North and the South.”

Of course, a state that imposes the respect of sanitary, environmental, and social norms in trade relations creates obstacles to trade. This also means that these obstacles are susceptible to be interpreted not as what they are or should be – the promotion of legitimate societal choices – but as a new form of protectionism.

Today, developing countries exert a great deal of pressure on developed countries to liberalize their agricultural policies, and this pressure will probably not enable multifunctionality or non-trade concerns to be put at the center of discussions because of their seemingly conflicting

nature with the non-trade objectives of developing countries.

Since the WTO Agreement on Agriculture, developed countries have been invited to open their borders not in order to encourage a modernized or more efficient agriculture but to favor agricultural models which, because of certain natural and social dispositions, permit cheaper production. But can the competitiveness of agriculture be still solely defined by its capacity to sell cheap agricultural products on the world market? And can the theory of comparative advantage, based exclusively on economic competitiveness and the lowest possible production costs, determine on its own the framework and substance of agricultural trade negotiations when agriculture needs to ensure food security, to guarantee the quality and healthiness of products, as well as to protect the environment and contribute to the vitality of rural areas? Given the challenges linked to sustainable development, economic competitiveness used as the sole criterion of international agricultural negotiations is now obsolete; agricultural prices should now also reflect the environmental and social cost of production.

Far from being a protectionist policy smoke screen, taking better account of the multifunctionality of agriculture constitutes a major evolution of agricultural policy toward good environmental practices and the objective of food security.

Summary

The agricultural question has once again become a geopolitical issue which will probably turn out to be increasingly complex given the demographic, environmental, and socioeconomic challenges of the twenty-first century. Over the next four decades, agriculture will have to face multiple challenges, and the test will be to introduce the social and environmental aspects of agriculture in international negotiations in order to guarantee its sustainability. Given the lack of consensus, the WTO has not yet managed to establish a dynamic negotiating process which is not limited to tariffs and subsidies, and this is probably the reason for the current deadlock in

the trade talks. Article 20 (c) of the Uruguay Round Agreement on Agriculture as well as the November 2001 Doha Ministerial Declaration requires that “non-trade concerns” be taken into account in the WTO negotiations. These social and environmental considerations of agricultural international law (food security, land access, and environmental concerns) refer, in fact, to the controversial concept of the multifunctionality of agriculture.

Introduction

The relations between ethics, agriculture, and multilateral trade organizations are complicated, both in terms of academic and policy debates. In the post-World War II period, the most powerful international trade institutions have been the General Agreement on Tariffs and Trade (GATT) (1947–1994), a treaty-based regime, followed by the establishment of a formal institutional structure in the shape of the World Trade Organization (WTO). Other agencies at the United Nations, notably the Food and Agricultural Organization (FAO) and the United Nations Conference on Trade and Development (UNCTAD), have interests in the links between agriculture and trade, but this entry will not debate these institutions. The discussion introduces and dissects debates that have revolved around the GATT/WTO system, divided into two main sections. First, there is a focus on political decision-making norms within the GATT/WTO system and how this culture shapes the scope for deliberation on agricultural

trade ethics. Second, the entry probes some major aspects of recent WTO agricultural debates, including attention to questions of subsidies and food security.

Institutional Practices and Agriculture in the GATT/WTO System

The management of agriculture as a multilateral trade concern has been intensely fought over in the postwar period. For most of the history of the GATT, particularly in light of the establishment of the European Common Agricultural Policy in 1962, agriculture was granted an exceptional political status. This took the form of two major measures: (1) the legitimization of subsidies as long as they were proven not to increase market share (GATT Article XVI:3) and (2) the normalization of quantitative restrictions which enabled, among other outcomes, the application of export limits to prevent critical shortages of foodstuffs (GATT Article XI:2). Thus, while it would be wrong to say that agriculture was excluded from all GATT proceedings, there was little political energy to unlock and negotiate wider trade in agricultural goods. It was only in 1986, with the launch of the Uruguay Round of trade talks, that agricultural law was codified into a particular agreement. In 1995, when the new WTO system assumed responsibility for monitoring the implementation of the Agreement on Agriculture (AoA), some trade experts, although by no means all, expressed optimism that a fairer regime of agricultural exchange could be established. By 2001, as part of the (still ongoing) Doha Round, WTO members agreed to reopen negotiations on agricultural trade rules in an effort to realize a diverse range of material benefits.

How such recent negotiations have been conducted is one important dimension for any ethical analysis of the nexus between trade and agriculture. Similar to other international organizations, the WTO has been troubled, at times acutely, by problems of “input legitimacy” or “procedural justice” that inevitably shape the scope for material rewards (Brown and Stern 2012; Elsig 2007). Particularly in light of

institutional debacles, such as the collapse of the Seattle Ministerial in 1999 amidst scenes of street protests, criticism has surfaced that the agenda-setting processes lack sufficient inclusiveness, transparency, and representation. Initially, such critics were found within particular governments, notably Southern countries such as Brazil and India, who grew tired of being diplomatically marginalized. Other prominent voices that condemned decision-making practices included national farming collectives and unions; research-informed civil society groups, such as Oxfam; and some policy-relevant scholars who were close to the Geneva-led policy process.

Three sets of debates can be highlighted here. First, as one prominent analyst has expressed it, the “major and unsustainable discrepancy” in the business of rule making and decision making at the WTO has always been the coupling of an automatic and binding system of laws under powerful surveillance with the informal, ad hoc practice of bargaining and negotiation (Narlikar 2005, p. 42). The importance of informal political practices in establishing agendas and codes of conduct within the WTO is impossible to overstate, a legacy drawn from the diplomatic “club” culture of the GATT. But when informality becomes the institutional *modus operandi*, weaker actors are always vulnerable to manipulation through forms of power (Narlikar 2005; Eagleton-Pierce 2013). Second, the need to perform effectively in negotiating arenas is closely tied to the technical resources and competences of each government. Historically, in terms of legitimacy, concerns lay in several aspects of the negotiating processes, including legal expertise, access to elite “green room” forums for select members, the core protocols on the negotiation of rules, issue linkages, and the role of the secretariat. Third, the question of representation remains a vexed problem: is the WTO’s legitimacy sufficient on the basis of the “collective” legitimacy of individual states (even when many may exhibit poor forms of domestic democracy and protest opportunities), or should the organization welcome greater parliamentary and civil society oversight and engagement? (Shaffer 2004; Charnovitz 2004). Whether one conceptually views this search for deliberative

legitimacy in terms of a focus on the optimal allocation of powers or, more amorphously, through multilevel governance within the system is one notable qualification.

Inequities in the organization and conduct of WTO agricultural talks have not, however, remained fixed. In 2003, at the Cancún Ministerial, three major Southern country coalitions arose to contest the tendency of the USA and the EU to monopolize decision making: the G20 (led by Brazil, India, and China) on offensive agricultural interests, the G33 (led by Indonesia and the Philippines) on defensive rural development concerns, and the Cotton-4 (Benin, Burkina Faso, Chad, and Mali) which targeted the removal of cotton-specific subsidies. Researchers have explored how these coalitions have worked to reconfigure the WTO negotiating environment. Within a largely positivist methodology, literature by Narlikar and Tussie (2004) and Odell (2006) has unpacked some of the factors behind effective coalitions, including comparing bloc and issue-specific groupings, the utility of material and diplomatic resources, leadership questions, and the means for managing criticism. Elsewhere, within a more critical sociological reading on symbolic power, Eagleton-Pierce (2013) has tracked how the G33 and Cotton-4 successfully drew upon different argumentation strategies in an effort to gain recognition in the WTO order.

Ethical Concerns and the WTO Agricultural Agenda

The very notion of “ethics” does not easily fit into the institutional vocabulary of the WTO’s agricultural agenda, nor do trade analysts and scholars commonly invoke it. The subject matter of neo-classical economics, which serves as a font of theoretical inspiration for most participants and knowledge producers on trade, has consistently eschewed explicit questions of ethics. This is regrettable given that classical political economists in a pre-disciplinary academy, such as Adam Smith, always incorporated ethics into their conceptual schemas. Nevertheless, one can point to ethical tensions and dilemmas that

resurface in negotiations over agricultural trade, even if such contests are conventionally explained through other concepts and guises.

Perhaps the starkest ethical concern has centered on the distributional effects of OECD government measures on resource-poor countries in the trading system. Many Southern countries have a disproportionate reliance on agricultural trade for export revenue, employment, and, by association in many instances, political stability. For instance, as a percentage of GDP, agriculture averages 10.3% in Southern countries, with an annual growth rate of 2.9%. By contrast, in Northern countries, the sector forms just 2.4% of GDP, growing only slightly by 0.8% per year (FAO 2006). In terms of the economically active population in Southern countries, 53% are engaged in agriculture-related work. Dependence upon the export of three or fewer agricultural products for foreign exchange remains a critical problem for many countries (FAO 2004). At the same time, Northern country support programs that restrict access to wealthy markets, generate large surpluses, and subsidize exports. Many critics have noted the transferring of government support funds to a concentrated number of large agricultural firms. For instance, according to the Washington DC-based Environmental Working Group, among subsidy recipients, the top 10% of US farms collected 73% of all subsidies (\$121 billion out of \$165 billion) from 1995 to 2005, an annual average of \$34,190 per recipient. In 2009, across the OECD as a whole, it was estimated that the value of support to producers was US\$252 billion (OECD 2010). Farmers in Southern countries are often excluded from these Northern markets and forced to compete against heavily subsidized competition in international and even local markets.

As a result of these material conditions, the political relevance of WTO negotiations on agriculture has been closely associated not only with efforts to close the Doha Round but also with the overall legitimacy of the WTO system itself. How the reform of the AoA is now intimately tied to notions of fairness or “diffuse reciprocity” in trading relations and, more broadly, international politics cannot be overestimated. Representatives

from Northern governments seldom miss an opportunity to preach the virtues of trade openness and external integration strategies with the capitalist system, while remaining resolutely protectionist themselves in key subsectors and categories. The agricultural rules in the WTO system largely perpetuate a system under which the distribution of agricultural trade is shaped not by comparative advantage in terms of competitiveness but by access to subsidies, an area in which privileged countries have an unrivalled advantage. While some modifications and policy reforms have been introduced by Northern members, failure to fundamentally change these conditions will inevitably reinforce a perception that WTO rules skew the benefits of trade towards the North. The degree to which the increased international awareness of inequities in trading relations actually impacts on the WTO agenda can be debated, but there is no doubt that the backdrop is considerably different compared to the years of the Uruguay Round.

Another related ethical tension involving the WTO agricultural agenda has pivoted around the relationship between definitions of food security and trade policy. The idea of food security was incorporated into the AoA text, but there have been criticisms that the notion largely privileges OECD country concerns. Within the preamble, Article 20, and provisions in Annex 5, food security is classified under what are called “non-trade concerns.” The basic premise behind this larger category is that agriculture serves many purposes beyond what is commonly recognized as “trade” – that is, the production and sale of commodities – and that such distinctions need to be acknowledged in multilateral rules. Since the conceptual debut of “non-trade” at the end of the Uruguay Round, the naming and classifying of topics under the heading has remained ambiguous. Countries have preferred to offer illustrative (rather than indicative) lists of “non-trade” items, going beyond food security to include ideas about environmental integrity or cultural preservation (Smith 2012). It is crucial to note that the dominant actors who shaped the legal meanings of food security in the Uruguay Round were not Southern members, but principally Japan, the EU, and the

Nordic countries. In subsequent policy debates, the EU’s heavy promotion of the concept of “multifunctionality,” characterized as a sub-category within “non-trade,” worked to complement and reinforce these meanings.

Yet, when analyzed holistically, there are perhaps more profound problems with how food security is conceptualized in the AoA. One only needs to glance at the vast academic and policy literature on the subject to appreciate that it is much more than simply government stockholding, a provision that can be exploited in the rules. Rather, the concept has been progressively stretched in multiple directions and spawned a variety of potential ideas. Since the 1970s, there have been changes in thinking that have reshaped what “food security” means: from the global and the national to the household and the individual, from a food-first perspective to a livelihood perspective, and from addressing objective indicators to subjective perceptions (Shaw 2007). The FAO’s (1996) definition often serves as a contemporary starting point for many analysts: “Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life.” Thus, the issue of food security may indeed go beyond the commercial model of farming and the supremacy of the price mechanism. As Aileen Kwa and Walden Bello (1998, p. 2) have argued in their critical reading of the AoA, “*real* food security raises questions such as who has access to the land, who produces, who makes the decisions, who will eat, and whether or not the food produced is culturally appropriate.” And yet these multiple perspectives and meanings, derived from a range of analysts, have found little home at the WTO, or at least not in its early life prior to 2000.

Since 2003, however, as a result of the efforts of the G33 coalition in the Doha Round, there has been some movement towards rethinking the nexus between food security and WTO policy. Research promoted by the FAO and civil society groups has also helped to spark and engender policy debates in this area. Although a Doha settlement has yet to be reached (and may never be),

the creation of the category of Special Products (SPs) in agriculture talks is still significant. SPs have provoked discussion on the limits of trade liberalization and how, in particular, Southern countries could protect certain critical goods from tariff reductions if it can be shown to benefit domestic livelihood security and rural development. Discussions between governments have centered on which products could be defined as “special,” how the evidence for differential treatment can be formulated, and what material consequences would be generated by such instruments. Major agricultural exporters, including the USA and the Cairns Group (led by Australia and Canada), have been most vocal in opposing SPs. But it is also important to recall that any implementation of SPs would result in significant disturbances in South-South trade patterns. For instance, Thailand, as the lead rice exporter in the world, has been concerned that other countries would specify rice as an SP. Malaysia also signaled that exports of its palm oil could be undermined if other countries, such as India, chose that product as an SP.

Summary

Researchers of WTO agricultural issues have historically not addressed their analytical problems through the category of ethics. At a deeper level, such a lacuna can be explained by how the major structures of knowledge production on international trade – neoclassical economics and law – tend to marginalize the unpacking of ethics. Yet despite this absence, analysts may deploy alternative conceptual vocabulary that grapples with certain ethical tensions and dilemmas in WTO agricultural debates. As noted, this has primarily surfaced in both scholarly and political discussions on the meaning of “fairness” and reciprocal exchange in trade talks. In particular, since 2003, coalitions of Southern countries have slowed down the pace of WTO political negotiations in order to defend their perceived interests. Within these moves, agriculture has come to dominate the Doha Round to a greater extent than was

envisaged by the EU and the USA. The AoA was a historical accomplishment in terms of its initial formulation, but it has left a tangled labyrinth of rules that in many areas legitimize government subsidies of rich countries. Internationally, access to such government measures will always be uneven, with distributional consequences in terms of competitiveness and livelihoods.

To conclude, there are some additional areas of research that need to be explored at the interface between ethics and WTO agricultural reform. First, in light of the ecological threat posed by a carbon-constrained world, scholarship needs to explore the extent to which WTO agricultural rules and practices contribute to forms of environmental injustice. For instance, at a higher level of policy abstraction, does the AoA promote a commercialized food system that is fundamentally unsustainable to ensure the preservation of agriculture? Second, and in a related sense, how can one analyze the emergence and material effects of biofuels in relation to WTO disciplines? If biofuels have been one contributing factor in commodity price volatility, including raising food import costs for resource-poor countries, what role does the WTO serve (if any) in limiting or managing such instability? A final under-researched area would center on larger questions of corporate or “market power,” including the financialization of trade in commodities. Further scholarship is needed to understand how major transnational agricultural businesses structure the scope for material impacts and work with political elites to further particular capitalist interests.

Introduction

The North American Free Trade Agreement (NAFTA) took effect on January 1, 1994. Ethical controversies arising from NAFTA policies, rules, and procedures reflect its character as more than a regional trade agreement designed to lower barriers to trade across US, Canadian, and Mexican borders. It offers far-reaching guarantees to the rights of foreign investors across NAFTA member state borders, including rigorous protection of intellectual property rights – exceeding World Trade Organization (WTO) standards. In particular, NAFTA prohibitions and sanctions against a

variety of “nontariff barriers” have raised ethical concerns about a threat to national sovereignty and democratic control in promulgating and enforcing domestic health and environmental regulations, including food safety standards.

Ethical concerns raised by NAFTA may best be framed as a failure of “moral imagination,” which Patricia Werhane (1999) defines as “the ability to perceive that a web of competing economic relationships is, at the same time a web of moral relationships” (p. 5). From this absence of moral imagination arises the all too common phenomenon of “moral amnesia,” which Werhane defines as “an inability to remember or learn from one’s own and others’ past mistakes and to transfer that knowledge when fresh challenges arise” (p. 7). As a consequence, “mental maps” or “cognitive scripts” that shape business decisions within the narrow confines of economic “rationality” tend to prompt a “setting aside of moral considerations in the pace of business activities” (p. 11).

Moral Amnesia and the Paradox of Globalization

This absence of moral imagination is suggested by Dani Rodrik (2011), a Harvard political economist, when he notes a “globalization paradox” whereby aggressive and inflexible extension of international free trade theory, embodied in a push for “*hyper-globalization*,” places constraints upon a nation’s sovereign jurisdiction and

democratic traditions. Such traditions sanction political intervention to buffer the negative impacts of economic forces or business activities upon social or environmental stakeholders. International trade economists and lawyers point to the hypothetical benefits of *unrestricted* global market production and exchange choices. This theory holds that regions, nations, and firms will prosper to the extent that their productive activities leverage a “comparative advantage,” grounded in favorable mix of “factor endowments.” Since factor proportions of labor, capital, and natural resources are assumed to be relatively static or fixed over time, it follows that entrepreneurs who engage in productive activities at locations with an optimal mix of factors will create opportunities for mutually advantageous specialization and exchange. When productive knowledge is included as a more dynamic or developmental factor, international intellectual property guarantees via patent, copyright, trademark, and trade secret protection provide corporations with incentives to develop and extend their “firm-specific advantage” across national boundaries (Smallson 1994). The favorable global and local welfare implications of international trade and production are said to reap “gains from trade” that are baked into the culinary metaphor of a “growing economic pie” and in the benign seagoing vision of a “rising tide that lifts all boats.” Rodrik questions the rigidity of this neoliberal trade policy formulation, pointing instead to the possibility of a more flexible international trade regime in which the hyper-globalization narrative is balanced by a regard for the legitimacy of national sovereignty concerns and the need for democratic oversight of the social and environmental impacts of international trade rules. This essay will adopt the complementary frames of analysis of Werhane and Rodrik with regard to the ethics of food policy within the NAFTA policy regime.

Tom Friedman’s Neoliberal Recipe for “Hyper-Globalization”

By way of contrast, Tom Friedman (2000) in his best-selling paean to neoliberal orthodoxy, *The*

Lexus and the Olive Tree, captures and strives to resolve the paradoxical tensions within the globalization narrative. The Lexus epitomizes the technological and material benefits of globalization, whereas the olive tree suggests the persistent appeal of local rootedness in culture, ethnicity, and a sense of place. Friedman stipulates the “golden rules” that frame the *golden straightjacket*. He insists that nations have no choice but to do this constraining garment, if they are to reap the alchemic benefits of “winner takes all” stardom on the “flat world” stage. He deems the straightjacket of a “free market” policy regime to be mandatory, since national “flexibility” in the application of golden rules would dim the stellar sheen of their global finery. This neoliberal nostrum of policy measures, also known as the “Washington Consensus,” stipulates that countries desirous of going global must remove cross border restrictions on trade and capital flows, privatize state-owned firms, rigorously pare back government regulations and social or industry subsidies that balloon government budget deficits, raise inflationary pressures against currency stability and convertibility, and stifle the “creative destruction” of capitalist innovation. When negotiating trade agreements, international trade experts decry calls for consideration of environmental, labor, or other human rights concerns on the grounds that environmental or social policy “side agreements” merely “muddy the waters” in striving for a “clean” economic trade pact.

In Tom Friedman’s globalization narrative, the *electronic herd* of long- and short-term investors is anointed as the bullish driver of global growth, spreading gold wherever nations and their denizens don their straightjackets like good global citizens. In the new sartorial era where “one size fits all,” Friedman finds a world where “your economy grows and your politics shrinks” (2000, p. 105). Policy initiatives are reduced to the choice between Coke and Pepsi as politicians exercise their “synchronized swimming” skills (p. 107). The threat of capital flight (stampede) out of countries that grossly violate the golden rules, or even a refusal by the electronic herd to graze in less inviting pastures, is taken to be a

formidable deterrent to removing or adjusting the golden straightjacket.

NAFTA trade courts have supported this hyper-globalization agenda by offering extraordinary reinforcement of the rights of capital enjoyed by the electronic herd within NAFTA via Chapter 11 trade courts. These tribunals provide oversight of national or local regulations that may threaten foreign investment profits in a manner considered “tantamount to expropriation.” They also have worked to “harmonize” member state regulation of environmental, food safety, and other health hazards that proponents of hyper-globalization challenge as potentially excessive and surreptitious nontariff barriers to international trade and investment.

NAFTA’s Chapter 11 Trade Court Protection of the Rights of Foreign Investors

NAFTA trade tribunals are designed to arbitrate private contractual disputes, even though Chapter 11 cases raise significant public policy concerns. NAFTA trade panels have held that “incidental interference” with the property rights of a foreign investor may constitute a “regulatory taking” that is “tantamount to expropriation.” In one celebrated case, a US firm, Metalclad, acquired a Mexican property that had been used previously as a hazardous waste dump. The local Mexican government refused to issue a construction permit until Metalclad had addressed local concerns about heightened cancer and birth defect rates by remediating a legacy of air and water pollution violations. Metalclad refused to agree to such remediation. The provincial government supported the local government stand by creating an ecological preserve at and around the waste site. Metalclad filed a Chapter 11 complaint and asked for \$90 million in damages from the Mexican federal government. The NAFTA trade court awarded Metalclad \$15.7 million in damages on the grounds that the Mexican government had violated the “minimum standard of treatment” guaranteed to foreign investors within NAFTA member states. The award was subsequently

reduced by \$1 million on procedural grounds (Public Citizen 2012).

In a similar case in California, a state regulatory agency banned the gasoline additive, MTBE (methyl tert-butyl ether), on the grounds that it had been determined to be carcinogenic under very low levels of contamination, if treated fuel leaked into the groundwater. A Canadian company, Methanex, sued the US government on the grounds that this state regulation was “tantamount to expropriation” in that it precluded potential profits from sale of the banned fuel additive. Even though this complaint was dismissed on procedural grounds, it still reveals an unresolved jurisdictional conflict between NAFTA trade courts and US (and other member state) legal systems. Article III of the US Constitution creates a federal judicial system. To preserve judicial independence, the Constitution holds that Congress cannot delegate the “essential attributes” of the judiciary. Yet it appears that this is what Congress did in creating the NAFTA trade court mechanism. The US Supreme Court has held that government regulations to protect the public interest do not constitute a regulatory taking if there is “incidental interference” with the rights of property owners to pursue profits (such as draining protected wetlands to grow crops). Yet this is precisely what NAFTA trade tribunals have asserted – and Chapter 11 rulings are not subject to appeal or oversight by the federal court system. US government agencies enjoy the right of “sovereign immunity” against lawsuits by its own citizens. However, the shield of sovereign immunity is notably absent in the case of potential damage claims by foreign investors in Chapter 11 trade courts. Successful Chapter 11 claims and settlements are still relatively modest at 35 million dollars as of 2007. However outstanding Chapter 11 claims amount to billions of dollars. Ultimately, US (or Canadian and Mexican) taxpayers are vulnerable to huge damage claims if this jurisdictional anomaly is not resolved in a way that restores national sovereignty and democratic control.

Moreover, the practice of resolving these investor claims and other trade disputes behind closed doors, without the right of interested

persons to testify, submit amicus briefs, or become a party to the suit is troubling, to say the least. Even the threat of a Chapter 11 complaint can chill public interest legislation. This was the case when the Canadian government withdrew proposed tougher warnings on tobacco ads, when threatened by a Chapter 11 claim by US tobacco interests. In a parallel case, the provincial government of New Brunswick in Canada dropped its proposal to offer low-cost public auto insurance after being threatened by a Chapter 11 claim by US auto insurance companies.

NAFTA's Downward Harmonization of Regulatory Standards

Harmonization of regulatory standards across national or local jurisdictions within NAFTA is intended to minimize anomalies that may create "nontariff barriers to trade." Since US federal and state regulatory standards tend to be more stringent than those of Canada or especially of Mexico, the outcome of harmonization is growing downward pressure on US regulatory standards. Moreover, NAFTA standards are presumed to be equivalent to international World Trade Organization (WTO) standards. Consistent with the hyper-globalization preference for resolution of trade disputes via secret adjudication by technical experts (letting economics grow and politics shrink), international regulatory standards are promulgated by secret trade panels of technical "experts." Since industry spokespersons can pose as "expert witnesses" to these panels, while public voices and outside scrutiny of secret testimony are denied, regulatory standards tend to be industry friendly and therefore less stringent in safeguarding against environmental or public health hazards. NAFTA decrees that food safety standards must be based on "scientific principles" and subject to risk assessments. Since there is little consistency among US food safety standards promulgated in different jurisdictions and over different time periods, US food regulations pertaining to exposure to pesticides, food additives, microbial contamination, and food

irradiation are subject to trade dispute challenges by importers of foodstuffs, opening the way to serious dilution of inspection standards and procedures. Thus, an absolute ban of a pesticide such as DDT could be challenged on the grounds that permitting trace amounts of the chemical would provide reasonable protection with minimal risk.

While harmonizing downward regulatory goals, NAFTA trade dispute resolution tribunals have also limited the means for achieving regulatory ends. NAFTA and the preceding US-Canada Free Trade Agreement require that signatory states allow imports subject to different but "equivalent" standards and inspection processes. Adopting this guideline, the United States stopped inspecting Canadian meat at the border for listeria contamination, accepting as equivalent a Canadian inspection of meat-packing operations more generally. Critics charged that these food safety regimes were not equivalent, since the rejection rate for Canadian meat imports dropped by half after the end of border inspections. NAFTA pressure to harmonize regulatory processes also poses a threat to the more stringent US inspection of Mexican fruits and vegetable imports, which tend to have higher residues of DDT and other pesticides (Goldman 1993, p. 4).

NAFTA does not allow import restrictions based on the adverse effect of a production process upon claims of environmental or health damage. A trade dispute brought by Mexico to WTO trade courts illustrates the potential ill effects of potential future NAFTA trade court rulings. The Mexican government charged in 2008 that US legislative and judicial rulings establishing the basis for restricting importation of tuna to those caught via "dolphin safe" means constituted a nontariff barrier to trade. A WTO appeals panel found that a US ban on Mexican tuna fishing practices which targeted areas in which dolphins were present discriminates against Mexican tuna exports to the United States. Such alleged discrimination was based on the WTO panel's finding that the US dolphin-safe law was "not even-handed in the manner in which it addresses the risks to dolphins arising from different fishing techniques in different areas of the ocean" (WTO Dispute Settlement DS 381, 12 October 2012, p. 4). The

perverse “logic” of such technical harmonization by a WTO (or potentially a NAFTA) trade panel undermines democratic control over national or local regulatory processes. It also undermines public policy efforts to preserve the global commons or endangered species. The adverse environmental and human impact of NAFTA rules on Mexican corn growers is another case in point.

NAFTA and Mexican Corn Farming

The NAFTA theory of comparative advantage justifies scaling back and eventual elimination of tariffs on protected Mexican maize production on the grounds that free trade conditions will create competitive pressures that reallocate human and natural resources toward their “highest and best use.” As productive resources shift toward different economic sectors that can gain advantage from more favorable factor proportions, free trade theorists argue that Mexico’s international trade competitiveness will improve. Developments on the ground suggest otherwise. Prior to the ending of protection for Mexican maize, three million small family farms (averaging five family members each) were occupied in maize production. Thus, 15 million peasant farmers and 7 million others engaged in transporting, distributing, and processing maize products were employed in this sector. NAFTA trade rules forced two million maize workers off of the land. Although one-quarter of Mexicans live in the countryside, they account for 44% of migrants to the United States. Most of the more mobile farmworkers were young men who sought their fortunes via illegal immigration north of the border. All too often, they sought their fortune in the illicit drug trade. Alternative jobs in seasonable vegetable and tropical fruit crop production failed to absorb many of the displaced farmers. The promise of growing labor-intensive manufacturing employment failed to materialize as domestic import substitution manufacturing jobs dried up and foreign investors tended to import components from abroad to take advantage of low-cost assembly in Mexico. When China joined the WTO in 1998, Mexico lost its labor cost advantage and the bulk of

labor-intensive assembly operations of the electronic herd shifted to Asia (Malkin 2009, pp. 1–3).

Ironically, as US corn imports to Mexico have risen from 7% of Mexican consumption in 1994 to 34% of consumption in 2011, the incidence of malnutrition in Mexico has risen sharply (Carlsen 2011, pp. 1–2). The bulk of these US corn imports have gone to agribusiness animal feed operations and to cornstarch production. Small family farms in Mexico are being displaced by the rise of large-scale government-subsidized agribusinesses in Mexico, as well as by surging US corn imports, which also benefit from substantial US government farm commodity subsidies. Such indirect government export subsidies of farm products from the United States and Europe have been challenged by developing countries in WTO trade talks, but to no avail. Thus, NAFTA trade rules have reinforced the “corporatization” of agriculture in the United States as well as Mexico. Corn production has actually increased in Mexico since NAFTA came into effect, but at the expense of small farm displacement and to the advantage of large corporate farms and food processors. This has had the effect of sharply increasing income inequality in Mexico while sapping the vitality of rural life as small farmers retreat to subsistence. Small family farmers cannot afford the expensive hybridized, often genetically modified, corn seed imports from the United States. Such seeds require more water, fertilizer, and pesticides in order to increase yields. Large agribusiness firms grow as small family farms are pushed to the margins (Johnson 2011, pp. 1–2).

The consequences for Mexico’s biological commons are also disturbing. US importation and planting of genetically modified seeds in Mexico are threatening the ancestral biological home of maize. Fifty-nine distinct cultivars of maize have been developed by indigenous farmers over millennia to adapt to different climatic conditions and cultural practices. The genetic diversity of these maize cultivars offers a robust biological defense against climate change or other ecological shocks. By way of contrast, the US factory farming practice of monoculture reduces food stocks to the status of a biological machine to be manipulated by chemical

fertilizers, pesticides, and even genetically engineered traits, such as pest resistance, to enhance agricultural “productivity.” Advocates of a more holistic and organic alternative model of food production point to the externality costs of factory farming methods, such as massive non-point pollution of the air and water commons, and the fragility of a monoculture food production model that depends on massive infusions of petroleum-based energy and chemical boosters to survive. Quite apart from the long-term threat to biological diversity posed by factory farming methods, a sharp rise in petroleum costs could undermine its economic viability over the short to medium term (Bollier 2010, pp. 1–2).

The point here is that NAFTA trade rules that focus on removing tariff and nontariff barriers to trade have seriously missed the boat in Mexico. Not all boats are rising and the economic pie, to the extent that it is growing, is being divided in ever more unequal slices. The social and environmental costs of NAFTA free trade policies are being ignored by a policy regime that exhibits moral amnesia by simply assuming hypothetical welfare benefits of hyper-globalization. A related form of moral amnesia (the inability to recognize the moral implications of economic decisions or actions) may be seen in NAFTA protection of intellectual property rights, a dynamic factor of production.

Ethical Implications of NAFTA’s Intellectual Property Rights Regime: The Mexican Yellow Bean Case

NAFTA was the first trade agreement to incorporate legal protection of intellectual property (IP) rights (see Smallson 1994). NAFTA’s Chapter 17 establishes minimum standards of intellectual property protection among member states, requires effective enforcement of IP rights at the borders of NAFTA states, and establishes a dispute resolution procedure with trade-related sanctions and in some cases damages, payable to IP holders if their rights are infringed. The intended effect is to reward innovation and promote economic development by harmonizing IP

protection mechanisms across Mexico, Canada, and the United States. Such IP safeguards would seem to be consistent with free trade principles of market access and nondiscrimination (Terry et al. 2005). However, ethical concerns arise if patent claims are placed on life forms that previously existed as a customary public good in a biological commons. Hence the growing controversy over corporate efforts to privatize the biological commons by patenting life forms, Critics have characterized this practice as “biopiracy.” This practice is especially prevalent in developing countries where private property rights are not well defined and where rich biological diversity and a wide range of customary practices in agriculture and medicine create opportunities for privatization of corporate “inventions.” Many poor farmers in developing countries are finding that they are required to pay licensing fees to grow crops native to their regions because large biotechnology and seed companies have patented their seed stock.

A notorious instance of such alleged biopiracy via the patent process is the Mexican yellow bean case. In the early 1990s, an American citizen, Larry Proctor, bought some yellow beans in a Mexican market, brought them back to Colorado, and crossbred them for several years to develop a variety which he claimed was patentable because of its more pronounced yellow color. He filed a patent for this “Enola bean” in 1996. The US Patent Office granted him a patent in 1999. This patent granted Proctor’s seed company, PODNERS LLC, an exclusive monopoly on yellow bean production and sale in the United States and potentially in Mexico and Canada as well. Exports of yellow beans from Mexico into the United States were immediately banned unless Proctor’s company was paid a licensing fee of six cents per pound.

The ethical (and legal) absurdity of this case is highlighted by the fact that the Enola bean was derived from Mexican seed stock and that yellow beans had been produced and sold for generations in Mexico. In 2001, the Spanish-based International Center for Tropical Agriculture (CIAT), whose mission is to catalog and preserve plant cultivars to maintain global and local biodiversity,

legally challenged the Ebola patent on the grounds that it failed to meet the US Patent Office's requirement that an invention should be novel, have utility, and be nonobvious. In support, a charitable NGO, ActionAid, filed a patent on chips (as in "fish and chips") to highlight the absurdity of the Enola bean patent claim (Rattray 2002). In December 2005, the US Patent Office rejected the Enola bean patent claim. However, Proctor appealed that decision and his appeal was rejected on April 30, 2008 (Wilson 2008).

While this common sense outcome suggests that misapplication of intellectual property laws can be remedied in the end, the lengthy process of review of the Enola patent claim seriously disrupted yellow bean exports from Mexico over a number of years. It also raised legitimate fears that rigorous enforcement of intellectual property rights could spur corporate profit making as much as real innovation. Privatization of the biological commons continues, typically without compensation to the traditional medicinal and agricultural practitioners who first developed or formulated the innovative use of life forms. Questionable and potentially unethical practices associated with privatization of life forms continue – such as the creation of "terminator seeds" that will not germinate after the first planting, so as to preserve sales of patented seeds. The use of "gene police" by seed companies such as Monsanto to prosecute or seek compensation from farmers whose crops have been pollinated by winds blowing over genetically modified food crops seems perverse as well. The grain growers of Alberta, as well as the maize growers of Mexico and organic farmers in the United States, feel justifiably threatened by this perverse form of enforcement of intellectual property claims.

NAFTA and Intellectual Property Controversies in the Pharmaceutical Industry

Efforts to control "gray market" imports to the United States of pharmaceutical products from Canada illustrate a curious interaction between Chapters 11 and 17 of the NAFTA treaty.

Chapter 11 empowers foreign investors to claim damages from sovereign states that impose regulations that indirectly limit profits in a manner deemed "tantamount to expropriation." Canadian medical care is provided, at least in part, as a public good available to all Canadian citizens. Hence, the Canadian government has taken steps to control the price of patented drugs that are formulated, often by US-owned subsidiaries in Canada, and sometimes made in the United States and exported to Canada. Whereas prescription drugs are sold at "market prices" in the United States, the Canadian government imposes price controls, administered by the Patented Medicine Prices Review Board. Prices for the same drug may be 50% lower in Canada than in the United States. As a result, a robust trade in prescription drugs has sprung up as Canadian internet pharmacies have responded to burgeoning US demand. In 2003, the value of this trade was estimated to be as high as \$1 billion. An unresolved intellectual property issue is whether patented drugs either made in the United States and exported to Canada or manufactured under license in Canada can be reexported to the United States without violating the US patent. Canadian federal and provincial governments do not legally sanction these internet pharmacy exports, but they have taken no steps to curb them. Thus, the Canadian governments appear vulnerable to a potential Chapter 11 lawsuit seeking damages for loss of profits due to their failure to enforce patent protections guaranteed under Chapter 17 of the NAFTA treaty. Canada is also vulnerable to an unfair trade practices claim because it does not force Canadian generic drug manufacturers to independently verify the safety and efficacy of their formulation, relying instead on the certification of the original patented drug. A Chapter 11 claim by US pharmaceutical companies against Canadian price controls of patented drugs is even conceivable. If internet sales of prescription drugs from Canada to the United States were legalized, as has been proposed occasionally as a cost-saving measure, both the US and Canadian governments would be vulnerable to a challenge of "unequal treatment" of Mexican pharmaceutical firms (Terry et al. 2005). Harmonization of

intellectual property standards to eliminate alleged nontariff barriers to trade can become a double-edged sword that cuts in strange ways.

Conclusion

The above discussion has demonstrated that NAFTA efforts to harmonize regulatory standards to minimize alleged “nontariff barriers to trade” can have perverse and possibly unanticipated effects. In particular, the hyper-globalization narrative that underpins NAFTA policy initiatives is unsympathetic to the claims of public health and environmental damage inflicted by the public policy constraints imposed by the golden straightjacket. Ironically, the golden straightjacket is not so much antiregulatory as it is regulatory in favor public policies that reinforce the rights of global capital (the electronic herd) and the single-bottom-line thrust of global corporations. The unequal, and certainly unfair, distribution of the costs and benefits of globalization lies at the heart of the controversy over the NAFTA and the ethics of food policy. When the stakeholders of global capitalism try to mobilize and exercise their democratic rights to call upon the power of the state to temper the social or environmental costs of a narrowly defined economic agenda, they are scolded by the apologists of hyper-globalization on the grounds that their democratic impulse is irrational, counterproductive, and likely futile as well. The result is a kind of “moral amnesia” (Werhane 1999) that seeks to marginalize calls for more fairness and balance in addressing social or environmental costs imposed by economic development.

Hyper-globalization is a unitary meta-narrative that seeks to drown out a cognitive scripts that would redefine “development” as a pluralist convergence of competing narratives to achieve improved and complementary economic, social, and environmental outcomes (the triple bottom line). Dani Rodrik (2011) has called attention to the “political trilemma” that confronts globalization. As currently framed, globalization may be compatible with either national sovereignty, via the golden straightjacket, or democracy via

creation of new forms of global democratic governance. Pragmatic reconciliation of these three constructs will require more openness and transparency in exploring and resolving policy differences, new democratic institutions that include and empower stakeholder dialog and engagement, and greater flexibility and balance in easing paradoxical tensions in addressing complex, “messy” problems (Calton and Payne 2003). Public policy controversies surrounding NAFTA and the ethics of food would be a good place to start in reimagining a more ethical global policy regime.

Introduction

Climate change and increased global population give rise to a special emphasis on how agriculture can expand production under changing conditions. Agriculture has also seen radical changes the last century with a turn towards research-based, industrialized agriculture with large-scale monocultures, mechanization, increased irrigation, use of artificial fertilizers, and pest control systems, combined with a change from local towards export-oriented making of products to be used for food, feed, fuel, and fiber. Biotechnology-based interventions such as systematic breeding, as witnessed in the Green Revolution, and genetic modification have led to commercially successful but politically controversial herbicide-tolerant and pest-resilient varieties of major crops, with promises of a wide range of new varieties in the years to come. In recent years nanotechnology methods and products have been added to the techno-scientific possibilities of improvements to agricultural production.

As yet, there are few if any commercially available products, but nanotechnology holds promises for increasing efficiency within animal and plant breeding; for increased nutritional value, and production inputs as feed additives, chemicals, and pesticides; for new efficient means for diagnosis and surveillance of diseases; as well as possibilities for precision farming techniques. Moreover, also with importance for agriculture is the possibility for using nanosensors for detecting and removing salt and pollutants from water and soil. Here some of these new developments will be briefly presented, with focus mainly on the agriculture production system and not on food products as such (packaging, detection of contaminants and pathogens, nano barcodes, etc.). New emerging technologies as nanotechnology can be used for solving problems as well as enhancing production and efficiency but do also raise questions with regard to food and environmental safety and socio-economic, ethical, and regulatory issues that will be highlighted.

Nanotechnology: Definitions and Uniqueness

Nanotechnology has some sociopolitical features distinguishing it from other emergent technologies. Some claim that it represents nothing new, being just a more attractive way to fund research and sell products derived from established practices in chemistry, whereas other novel technologies have had clearly defined characteristics. Therefore, there have been several claims of the field being built on hype more than realistic hope – with similar hyperbole regarding potential hazards (see, e.g., Nordmann 2007 and Wullweber 2008). In addition, the introduction of nanotechnology to the general public was accompanied with a call for ethical assessment, implying that the potential of the technologies is directly connected to the risks (The Royal Society and the Royal Academy of Engineering 2004). Consequently, it can be argued could even claim that this focus on potential hazards give support to the claims regarding potential benefits. These special characteristics of this technology can also be found in the literature on agricultural nanotechnology.

There are different definitions of nanotechnology. The interest in nanotechnologies is linked with the possibility for manipulation of material, devices, and other structure on an atomic and molecular scale. The National Nanotechnology Initiative in the USA defines the scale range for nanotechnology where at least one dimension has the approximate measure of 1–100 nm. Nanotechnology describes the creation and utilization of functional materials, devices, and systems with novel functions and properties that are based either on geometrical size or on material-specific peculiarities of nanostructures. The nanoscale has become accessible both by application of new physical instruments and procedures and by further diminution of present microsystems. Also structures of animated and non-animated nature were used as models for self-organizing matter (<http://www.nanoforum.org> “What is nano?”).

There are numerous patents and several nanomaterials and nanoparticles have reached the market (<http://www.nanotechproject.org>);

however there is little as yet directly applicable to agriculture. The field is largely unregulated and some products are advertised as nano without falling within the defined scale, whereas others that could be thus classified carry no indication that the product contains nanomaterials. Hence, the definition of nanotechnology is arguably also of legal significance because of the connected consequences for future regulatory regimes. It is reasonable to believe that regulatory mechanisms as well as labeling will be important issues when products derived from agricultural nanotechnology reach the market. The public conception and acceptance of nanotechnology will be decisive for the labeling strategies chosen by the industry.

Animal and Plant Breeding: New Possibilities with Nanotechnology

Breeding to achieve more productive animals and plants is of crucial importance in order to solve the future food challenges. At the same time, climate change has caused an increased focus on stress-tolerant plants, new modes of agriculture, as well as conservation agriculture. Traditional ways of breeding is time consuming and has caused a special interest in possibilities with biotechnological methods, and this has recently been expanded to include nanotechnology.

Convergence of Nano- and Biotechnology Techniques

Special focus has been on the possibility to enhance present genetic engineering techniques by using nanotechnology for improving precision. Nanotechnology may reduce time and cost of gene sequencing, improving the basis for genetic modification or directed breeding (Chen and Yada 2011). Nanotechnologies can also be used in the genetic modification process and even be involved in synthetic biology efforts to create novel plant varieties (Scrini and Lyons 2007). Examples of such combinatory methods include crystal DNA and magic bullets (silica particles) that deliver genes to specific parts of plant or plant tissue, already used in plants (tobacco and maize).

Through these combinations of technologies, new properties such as tolerance to drought, saline earth, low or high temperatures and other extreme conditions, altered growing seasons, better pest resistance, altered colors, and so forth be introduced faster and with more precision using options with nanotechnologies than by present-day techniques.

Functional Food and Feed

Different strategies can be used to enhance and alter nutritional components of food and feed. The first includes using nano-encapsulation techniques either for controlled delivery of micronutrients and bioactive compounds already found in food and feed (Sozer and Kokini 2012) or to alter the composition of nutrients and flavor to meet special preferences or physiological requirements (Chen and Yada 2011). Improvement of nutrients as, for example, omega 3 and omega 6 fatty acids, probiotics, and vitamins is also possible in relation to change in delivering properties and solubility. By provision of specific bindings with mycotoxin, aflatoxin, and pathogens, nano-sized additives can be used to reduce toxic impacts and disease in consumers (FAO and WHO 2010).

Examples of food products that are already on the market include a new variety of rapeseed containing tiny materials that can block cholesterol from fat entering the bloodstream (Farhang 2007), nano-iron in nutritional drinks, and nano-minerals in breakfast cereals (Sozer and Kokini 2009). Whether all these should be called nanotechnology applications probably depends on the definition. There exists as yet no consistent regulation of these nanotechnology food additives (ibid.) although there is considerable ongoing work to develop the basis for regulation (Duvall et al. 2011).

Plant Production

Nanotechnology holds potential for increased plant production and for controlled agriculture practices.

Field Sensing Systems

Nanosensors can be used to facilitate real-time monitoring of the crop growth, field conditions, environmental stressors, and crop conditions (Chen and Yada 2011). Such field sensing systems, also called precision farming, can be used for identification of the right time to plant and to harvest and for detection of pests, viruses, weeds, or temperature and humidity changes as well as monitoring of soil nutrients. This can be facilitated by connecting nanomaterials working as sensors with global positioning systems or through network of wireless nanosensors in a field (Chen and Yada 2011; Nanoforum 2006). Once changes are identified, targeted measures can be initiated as application of pesticides, fertilizers, and irrigation.

One of the benefits by introducing field sensing systems in present agriculture practices is the potential for increased precision with the potential result of less use of chemicals. This will cause lower production costs and less adverse effects on the environment. Another benefit is that such monitoring systems can also be used to achieve increased understanding of the physical, chemical, and biological interactions between plants and pathogens that subsequently may lead to better treatment strategies.

Nanoscale Delivery Systems and Formulations

Within medicine the use of nanoscale delivery system has shown great promises. This has led to questions whether the same approach can be used for controlled delivery within agriculture of products as fertilizers, pesticides, herbicides, plant growth regulators, etc. The mechanism behind such nanoscale delivery systems is within the use of encapsulation, polymers and dendrimers, and surface ionic and weak bond attachments. By these mechanisms improved stability can be achieved and hence lesser amount of the products needs to be distributed and thereby results in reduced chemical runoff and environmental degradation. Formulations that contain nanoparticles within 100–250 nm size range are already in use in agriculture. These formulations have gained increased ability to dissolve in water with the impact that their activity is increased (Nanoforum 2006). Other

applications are nano-emulsions with herbicides or pesticide particles in the range of 200–400 nm that have gained increased integration properties in gels, liquids, and creams that ease distribution. One example of a such nano-emulsion is a product marketed by Syngenta that releases its insecticide when it comes in contact with the alkaline environments that are in the stomach of certain insects.

EHS for Farmers

The different formulations containing nanoparticles that are already on the market are not labeled (Scrinis and Lyons 2007). They have been developed with the intention to increase capacity for absorption into plants compared to larger particles. These altered properties imply novel health risks to farmers as well as animals that need to be investigated. The current state of scientific uncertainty regarding these potential hazards implies that a precautionary approach is warranted.

Diagnostics and Vaccines

Diseases within agriculture are causing economic problems for farmers and are affecting animal welfare. Nanotechnology hold promises for developments within vaccines and with regard to detection and diagnostics of diseases. There has been a shift in focus within vaccine research to the design of delivery systems that are able to mimic pathogens in size and composition. Examples include virosomes, liposomes, and polymeric nanoparticles (Panda 2012). Such structures can contain specific drugs that are delivered at the intracellular level to obtain desired and optimal immune responses against a given pathogen. The use of polymeric micro- and nanoparticles in vaccine delivery systems represents at present a highly studied approach (Lü et al. 2009). Drug nanocarriers may also be developed by using polymers, albumin, gelatin, alginate, collagen, and chitosan that also are biocompatible and are biodegraded at different rates after vaccination.

The use of a biosensor composed of a biological component as a cell, enzyme, or antibody linked to a wireless device can be used to detect changes within cells and molecules and produces

when activated by binding a signal that is proportional to the quantity of the substance that is recognized. The use of such nanosensors also opens up for real-time information about animal health status as well as early detection of animals with diseases. These animals can be isolated before the disease becomes a serious problem within the holding (Evers et al. 2008).

Environmental Remediation and Detection

Modern agriculture methods including industrialized agriculture have seriously affected surrounding environments. Nanoparticles can be used as means for degradation of pollutants (Baruah and Dutta 2009), for example, by photocatalysis, using metal oxide semiconductor nanostructures, organic pesticides and industrial pollutants can be degraded into benign environmental components. The same approach can be used for desalination and purification of soil and water. The detection of the abovementioned contaminants can also be facilitated by nanotechnology, using electromechanical and optical sensors. However, there are toxicity and stability issues, making the range of possible applications uncertain at the current stage of technology development.

Food, Animal, and Environmental Safety

Concerns about the adverse effects of nanoparticles and nanomaterials on the environment and human health are primarily related to the following characteristics (The Royal Society and the Royal Academy of Engineering 2004):

- Their large surface area, crystalline structure, and reactivity, which can facilitate transport in the environment or the body.
- Ultrafine particles may have a different biological behavior and mobility than the larger particles.

Within the past years, an increasing number of requests for toxicity studies have been raised;

however, there are still only a few ecotoxicity studies that have been published. Although some of them have provided empirical evidence that occupational and environmental exposure to nanoparticles can lead to adverse health effects on living organisms, there is still need for the establishment of methods and approaches for identification and for evaluating the risks of harm to environment and human health. The size of the particles in itself is also of importance, especially when considering that such particles could accidentally and without notice be distributed to living systems through air, soil, and water.

Distribution and Persistence of Nanoparticles

Nanoparticles can enter the body via the digestive tract by ingestion and drinking, the lungs via the respiratory tract, and possibly the skin through dermal exposure. Once in the body, nanoparticles can be redistributed to organs or tissues through the blood circulation or by cell migration. For some of the new approaches as the use of nano-carriers in vaccine delivery, there are unresolved issues related to unintended effects as, for example, effects by distribution to nontarget organs and cells. There is a great need of information about likely exposure levels, dose–response relationships, modes of action, and fate in the environment, the mechanisms of toxicity, and processes of elimination and accumulation of nanoparticles (Grieger et al. 2009).

Animal Welfare Issues

With the introduction of new technologies, there can be conflicts and trade-offs between short-term profit of the industry and demand for cheap animal products on one hand and animal welfare on the other hand (Olesen et al. 2010). The possibilities within breeding of animals with nanotechnology will as with other breeding strategies focus on the goal to enhance characteristics and traits such as productivity and growth. However, it is also important to be aware that the pursuit of such goals may deteriorate awareness for low heritable traits such as health, welfare, and fertility. Due to the significant lack of knowledge concerning

potential threats to health and environment, it is possible that the use of nano-based feed and drug delivery technologies may result in serious animal welfare problems. There are insufficient grounds for saying that it is scientifically plausible that such products will cause harm, but the lack of knowledge implies that it is reasonable to argue for a precautionary approach to the use of nanotechnologies in animal feed and medication, although that is disputed (Lin 2007; Evers et al. 2007).

Environmental Issues

Nanotechnological products intended for use in agriculture can spread, persist, and end up as environmental problems. For example, the size and dissolvability of nanoparticle pesticides imply that they can contaminate surrounding soils, waterways, and food chains and be ingested or taken up by living organisms (Scrinis and Lyons 2007). Nanoparticles are already part of the natural environment, but there is insufficient knowledge of how novel laboratory-produced nanoparticles will behave when released in vivo. Both the time they remain in air and the time they use to dissolve or break down can be significantly different from that of larger particles. Several authors have pointed out that although the knowledge of environmental effects is largely unknown, the research funding for research in environmental impact is low.

Ethical Issues

Agricultural nanotechnology is aiming at contributing to solving pressing problems of the future of humanity. As such it is ethically good pursuing this research and development. However, it is known from history that good intention is not sufficient; it is still necessary to ask what kind of technology and type of applications will contribute to a good future. Thus, this is an ethical matter. Ethical issues can be classified as intrinsic and extrinsic, the first being those that concerns the moral value of the activity in itself and the second

those that relate to the moral value of the context and the effects of the activity. Food production plays a crucial role in human life and is a central part of culture. This is evident in the controversy connected to biotechnology in agriculture, where a series of surveys show that the general public and farmers find this kind of technological intervention to be morally unacceptable for intrinsic reasons. The objections are typically expressed as in terms of the technology being unnatural or represents playing God. Both convergence of nanotechnology with gene technology and other nanotechnology interventions share the characteristics making gene technology considered unnatural. Despite general scientific and philosophical objections concerning the factual and conceptual problems with the naturalness argument, it remains a challenge for bio- and nanotechnology in agriculture.

The main extrinsic concerns are connected to issues of risk and scientific uncertainty concerning possible harm to human health and to the environment on the one hand, as discussed above, and socioeconomic and political aspects of the technology on the other hand. Unresolved risks as well as awareness of scientific uncertainty with nanotechnological applications call for implementation of the precautionary principle in decision-making processes. To improve the basis for decision making, risk-associated research needs to be carried out. In practice such research implies a combined scientific and ethical analysis, where scientific research integrates social science as well as ethics perspectives on the relevant science and technology (Myhr and Myskja 2011). The goal must be to ensure a responsible development and introduction of nanotechnology in agriculture.

Socioeconomic Issues

The intention by introducing new technologies in agriculture is to increase food production and enhance production security. However, new technologies may also increase corporate ownership and alters the economic control between different actors within the agriculture system (Scrinis and

Lyons 2007). This has been pointed out in numerous articles on industrialized agriculture, and is one of the key issues presently discussed in relation to the introduction of modern biotechnology on farming practices. These tendencies towards a “bioindustrial paradigm” can be further strengthened by agricultural nanotechnology, since some of the new developments as convergence of nano- and biotechnology within breeding and field sensing system can be best suited for large-scale farmers in the developed world. Moreover the benefits from, for example, precision farming systems can only be achieved in advanced and intensive agriculture systems.

It follows that the turn towards nanotechnology primarily benefits the large-scale farmers in the rich parts of the world. If this is correct, nanotechnology in agriculture is yet another element in present allegedly negative tendencies. In the rich world, the corporate farm is replacing the small family farms. On a global scale, it contributes to the technology divide, widening the gap between rich and poor. Therefore it is crucial that institutions that are involved in developments of nanotechnological applications for agriculture also emphasize how the new possibilities can be used to enhance food security for small-scale farmers and how to meet challenges in agriculture in the developing world. Capacity building is necessary both with regard to the technology in itself and also with regard to assessment and management of risks for health and environment.

Summary

Nanotechnology has a great potential for increasing efficiency within agriculture and for solving problems related to climate change, diseases, and pollution. At the same time, it is important that, potential risk and concerns about unforeseen adverse effects need to be taken seriously and should be reflected in regulatory frameworks. Regulators needs to be aware that the unique properties of nanotechnological products may also represent new risk and thereby raise the following important questions: Are the present test procedures good enough? Are the laws good

enough? Should a precautionary approach be employed? To cope with potential uncertainties and risks, innovation processes need to be combined with approaches that have inbuilt awareness for risk to environment and health of both farmers and consumers. The success or failure of nanotechnological applications will depend on market and consumer acceptance. As with GMOs it can be expected that nanotechnology in agriculture and food products will be received differently because of national and local sensitivities, traditions, and social and political cultures. To build farmer and consumer trust, it will be necessary to label both the inputs into agriculture, as new types of pesticides, as well as the food product before it is available in the local grocery.

Introduction

National courts can play a key role in the advancement of the right to food by ensuring that the right is upheld and through providing redress to individuals whose rights have been violated. However, while the right to food has been enshrined in international law since 1948, it is only over the past 20 years that the international community has sought to clarify the content and scope of the right and that states have begun to adopt the right into domestic legal systems. Right to food litigation is still in a nascent stage of development, with a growing but still limited number of domestic courts around the globe having expounded upon its tenets or made findings of violations. Nevertheless, there have been cases where litigants have claimed violations of the right to food and where courts have made significant rulings. This entry outlines the content of the right to food, the role national courts can play in implementing and enforcing the right to food, and what courts have done to date. It also offers some brief comments on the controversies of using national courts in the promotion of the right to food and highlights possible developments that may be seen in the future.

Background on the Right to Food

The right to adequate food is a human right enshrined in the Universal Declaration of Human Rights (UDHR) (Article 25), the International Covenant on Economic, Social and Cultural Rights (Article 11) (ICESCR 1966), and a host of other international instruments including the Convention on the Rights of the Child (Articles 24(2)(c) and 27(3)) and the Convention on the Elimination of All Forms of Discrimination against Women (Article 12(2)). The right to adequate food, as part of the right to an adequate standard of living, “is realized when every man, woman and child, alone or in community with others, has physical and economic access at all times to adequate food or means for its procurement” (UNCESCR 1999). The right to food protects the right of all human beings to feed themselves in dignity, either by producing or by purchasing food.

States are the primary duty bearers with respect to the right to food. Specifically, states have three substantive obligations flowing from the right to food – the obligations to respect, protect, and fulfill the right to food. The obligation to *respect* requires the state to not engage in activities that hinder access to food. The obligation to *protect* requires the state to ensure that third parties do not hinder the ability of people to grow or purchase food. The obligation to *fulfill* requires the state to ensure that no one goes hungry, even during times of emergency, and to engage in remedying systemic structural causes of food insecurity. States are also required to follow a number of procedural requirements and must ensure participation of the population in the development of policies, programs, and laws and nondiscrimination throughout the implementation process.

While the right to food was first articulated in 1948 in the UDHR, it was not until the mid-1990s that states began to adopt and implement the right to food in the national context. The adoption of the right to food corresponded largely with efforts by the international community to clarify the content of the right to food and the means for its implementation through General Comment

No. 12: The Right to Adequate Food and the *Voluntary Guidelines to Support the Progressive Realization of the Right to Adequate Food in the Context of National Food Security*. These documents stress adopting domestic framework laws, monitoring mechanisms, and remedy procedures and outline unique roles in the protection and promotion of the right to food for the legislature, executive, and courts (UNCESCR 1999; FAO 2004).

With respect to national courts and the role of national courts in the implementation of the right to food, General Comment No. 12 provides that “[a]ny person or group who is a victim of a violation of the right to adequate food should have access to effective judicial or other appropriate remedies,” specifically restitution, compensation, satisfaction, and guarantees of non-repetition (UNCESCR 1999). It urges the incorporation of the right to food into domestic instruments, in part because incorporation “can significantly enhance the scope and effectiveness of remedial measures” (UNCESCR 1999). Through incorporation, courts are “empowered to adjudicate violations of the core content of the right to food by direct reference to obligations under the Covenant” (UNCESCR 1999).

States can afford legal protection of the right to food in a number of ways. Some states, such as Argentina and Norway, grant international law and treaties such as the ICESCR constitutional rank and as a result implicitly guarantee the right to food (De Schutter 2013). However, the most common way that states have adopted the right to food is through constitutional protection and the adoption of right to food framework laws. Constitutional rights serve as governing principles for states and, depending on the domestic legal system, cannot be derogated from. To date, over 20 countries, including South Africa, Brazil, and Kenya, have amended or adopted constitutions to include the right to food. Right to food framework laws, such as those in Guatemala, Ecuador, Venezuela, Nicaragua, and Honduras, can also provide legal protection of the right to food – often in a more coordinated and detailed fashion than through constitutional protection.

The Role of National Courts in the Adoption of the Right to Food

Where the right to food has been adopted into the domestic legal system, courts can serve as key monitoring agents of the domestic laws and constitutional provisions, providing a venue for the review of government action (or inaction) by individuals or groups within the state. In this way, domestic courts provide an accountability mechanism, holding the government accountable for human rights violations and protecting the social contract between individuals and the state. While every jurisdiction may provide courts with different powers, the following list speaks in a broad fashion to how a national court may engage in the promotion and protection of the right to food:

- First, as independent interpreting agents, courts define the scope and content of domestic obligations whether constitutional, legislative, or drawn from international law. Courts, particularly in common-law jurisdictions, may define what constitutes the right to food in their jurisdiction, or provide a test for what would constitute a violation of the right to food. Through the interpretation process, courts can significantly advance the right to food.
- Second, courts can ensure that domestic laws and regulations do not conflict with the requirements of the right to food. Where conflicts do exist, courts may have the competence to direct how laws and regulations are implemented or interpreted and may even have the ability to strike particular sections or the entire legislation or regulation, where the sections or entire law violate human rights. This is particularly the case in states where there is constitutional protection of the right to food.
- Third, courts can address specific violations of the right to food, be they violations of the obligation to respect, protect, or fulfill the right to food. Courts can require the government to refrain from acting in certain ways, to act proactive in others (e.g., provide food, draft laws or regulations, develop programs or

policies), or to restrict third parties. Courts can also order remedies for victims of right to food violations and review the implementation of social protection schemes or other programs (such as school feeding programs or rural extension services) to ensure, for example, nondiscrimination in the provision of services or the participation of affected communities in policy-making.

Litigating the right to food through national courts, regardless of the outcome, can also help to promote the right to food by raising public awareness. Litigation through national courts can be a tool for advancing the right more broadly by educating the public, bringing attention to particular issues, providing information about rights to a wider audience of right holders, and creating alliances or solidarity among the public. Using national courts can also form part of a greater strategy for advancing the right to food – one that combines public campaigns for legislation and national policies, political and legislative lobbying, or demonstrations and public awareness activities (Cohen and Brown 2005; Courtis 2007). For example, the Right to Food Campaign in India, an informal network of individuals and organizations “committed to the realisation of the right to food in India,” has worked alongside a piece of litigation to raise awareness and push for legislation on the right to food (Cohen and Brown 2005).

National Courts and the Right to Food: Examples

A growing number of states have granted legal protection for the right to food, many of which are highlighted above, but courts, as of yet, have only heard a limited number of cases concerning the right to food directly (Knuth and Vidar 2011; De Schutter 2012a, b; Golay 2009). These cases, however, provide clear insight into how national courts promote and address violations of the right to food and how they could continue to do so in the future.

The most notable right to food case in a national court comes from India. The case *People's Union for Civil Liberties v. Union of India and Others* was initiated in 2001 in response to the government's failure to distribute employment and food relief mandated by the Rajasthan Famine Code of 1962 (Writ Petition 2001). Specifically, the case was brought against the Government of India, the Food Corporation of India, and six state governments on the basis that these government entities failed to address hunger and starvation-related deaths in a time of surplus and in violation of existing laws, programs, and the Constitution (Birchfield and Corsi 2010b). While there is no express provision in the Indian Constitution guaranteeing the right to food, the litigants relied on a constitutional precedent, which defined the right to life, under Article 21, as including the right to adequate nutrition (Birchfield and Corsi 2010a).

In the last decade, the case, which is still ongoing, has expanded in reach, encompassing all state governments, and scope, focusing on larger systemic issues of food insecurity, poverty, and unemployment (Birchfield and Corsi 2010a). The Supreme Court has issued a series of significant interim orders that have recognized a constitutional right to food, identified a number of food schemes as legal entitlements, determined a basic nutritional floor, and provided directives in the creation, preservation, and proper implementation of various programs, such as the national Mid-Day Meal Scheme (providing food in school) and the Public Distribution System (delivering grains to people in extreme poverty) (Birchfield and Corsi 2010b). The Supreme Court also established new accountability mechanisms, in particular, a new commission to monitor and report on noncompliance with court orders related to the right to food. Following the efforts of the commission, the Court, and a civil society campaign (entitled the Right to Food Campaign), a participatory process to draft national legislation to codify the various entitlements achieved through the interim orders was initiated by the government. On July 5, 2013, the government adopted the National Food Security Ordinance (Birchfield and Corsi 2010b; De Schutter 2013).

The case is an example of how courts can address the obligation of states to *protect* and *fulfill* the right to food, as well as ensure nondiscrimination and the effective provision of laws, policies, and programs. It is also a prime example of how national courts, litigation strategies, and effective public advocacy, when combined, can be most effective in promoting the right to food.

While other cases have been less spectacular in their reach, length, and scope than the *People's Union for Civil Liberties* in India, there are numerous other examples where courts have actively engaged with the right to food. First, a number of courts have provided a venue for the review of government action (or inaction). In one example, the Sectional Court of Appeal in San Pedro Sula, Honduras, enforced the state obligation to *protect* the right to food by granting a constitutional remedy to prevent the eviction of a peasant group, Brisas del Bejucó, from the land they relied on for subsistence agriculture (De Schutter 2013; Cruz 2010). The Court, referring to the obligation of the state to protect the right to food, as outlined in the ICESCR, affirmed that evictions would lead to human rights violations and voided the eviction order (Cruz 2010).

In another example, the High Court in Uganda at Kampala enforced both the obligations to *respect* and *protect* the right to food to address not only state action but also the failure of the state to prevent the actions of a private enterprise (De Schutter 2013). The Court ruled in March 2013 on behalf of 2041 peasants primarily engaged in subsistence farming in Mubende, Uganda, who were brutally expelled from their homes and farms in the summer of 2001, so that their land – land they depended on to meet their food needs – could be leased to Kaweri Coffee Plantation Ltd., a solely owned subsidiary of the Neumann Kaffee Gruppe, headquartered in Germany (Baleke and et al 2002; De Schutter 2013). The Court held that the state agents were liable for violations and ordered that compensation be paid to the peasants. In addition, the Court held that investors “had a duty to ensure that . . . indigenous people were not exploited. . . . They should have respected for the human rights and values of people and as honourable businessmen and investors

they should have not moved into the lands unless they had satisfied themselves that the tenants were properly compensated, relocated, and adequate notice was given to them” (Baleke and Others 2013).

Courts are also able to review government legislation or programs, particularly in countries with constitutional protection of the right to food, for compliance with right to food principles. While not directly a right to food case, an example from South Africa illustrates how courts can examine legislation for its impact on the ability of people to meet their food needs. In *Kenneth George and others v. Minister of Environmental Affairs and Tourism*, a number of fisherfolk challenged the Marine Living Resources Act, which favored commercial fishing over small-scale traditional fisheries resulting in many communities of small-scale fisherfolk losing access to the ocean and, therefore, their primary source of food and income. They alleged the government had failed to *respect*, *protect*, and *promote* their right to food by not only failing to improve but also reducing their access to food (Jaffer 2007). In 2007, the High Court, ruling on equality grounds, and not the right to food, provided remedies to the fishing communities and mandated the government to create a participatory and inclusive task force to prepare a new legislative and policy framework that would “take into account international and national legal obligation and policy directives to accommodate the socio-economic rights of these fishers and to ensure equitable access to marine resources for those fishers” (Kenneth George and Others 2007). Following the court order, a committee was formed, and on May 4, 2012 after a public consultation process the Small Scale Fisheries Policy entered into force (De Schutter 2012a).

Many of these examples also illustrate how courts have addressed individual violations of the right to food, as well as failures of states to meet their obligations to *fulfill* the right to food. Other examples include a recent case from a juvenile court in Guatemala concerning five children in two villages who were left malnourished as the result of the state’s failure to *fulfill* the right to food and provide needed support. In the decision,

grounded in Guatemala's Food and Nutrition Security Law, adopted in 2005, as well as Guatemala's obligations under the ICESCR, the court ordered 10 government institutions to adopt 26 specific measures including restitution and compensation measures such as food assistance, land distribution, water access, and agricultural training (FIAN 2013; De Schutter 2013). Another example comes from Nepal, where the Supreme Court in *Pro Public v. Government of Nepal* issued an interim order in 2008 to address the immediate need of several communities that were not being reached by food distribution programs already in place. The basis of the claim was a provision of the 2007 Interim Constitution of Nepal, which guaranteed a right to food sovereignty, as well as Nepal's obligations under international law to fulfill the right to food (Pro Public 2010).

Beyond the national court context, the right to food has also been upheld in regional human rights courts. In 2011, the African Commission on Human and Peoples' Rights (ACHPR) found inter alia that the Nigerian government had violated their obligation to *respect* and *protect* the right to food of Ogoni communities by both destroying and allowing third parties to destroy their food sources and causing environmental contamination and degradation (SERAC et al. v. Nigeria 2002). Further, the Inter-American Court of Human Rights in the 2006 decision in *Comunidad Indígena Sawhoyamaya v. Paraguay* considered whether the right to food constituted an integral component of the right to life (Cruz 2010). Finally, the Court of Justice of the Economic Community of West African States in 2012 found that groups have protected rights to the resources they depend on for an adequate standard of living, including the right to food (SERAP v. Nigeria 2012).

Challenges and Controversies to Utilizing National Courts to Enforce the Right to Food

Using courts to advance the right to food poses particular challenges. The first set of challenges relates to the practical realities of using national

courts as a means for advancing and protecting the right to food. These challenges include:

- *Access to justice:* The cost of bringing a legal action in a national court can be exceedingly high. Litigants must pay court fees, disbursements, and lawyers. However, right to food violations are often experienced by the most marginalized and poorest members of society, for whom the ability to bring an action in a national court or to even access a lawyer may be highly limited. Similarly, the majority of the world's hungry are rural smallholder farmers and peasants in the Global South (IFAD 2011; Hirsch et al. 2009). Ensuring access to justice in rural communities may pose even greater challenges than in cities for the purely logistical reason of availability of lawyers and ability of lawyers to reach communities.
- *Access to knowledge:* Access to knowledge about what constitutes a violation of the right to food can be key in a community or an individual's ability to mobilize. In the *Brisas del Bejuco* case in Honduras, for example, arguments made on behalf of the community were based on knowledge learned by a community member at a right to food training course (Cruz 2010). Without this knowledge, the community may not have known there was even a cause of action to advance and may not have sought legal assistance.
- *Speed of litigation:* Litigation and the enforcement of rights through national courts may be effective, but it will likely not be speedy. For example, in the *Mubende*, Uganda case, the peasants concerned were evicted in 2001, filed a court action in 2002, and finally received a verdict in their favor on March 28, 2013 (H.C.C.S. No. 179/2002; De Schutter 2013). While courts can order interim injunctions or interim remedies, as was done in the *People's Union for Civil Liberties* in India and *Pro Public* in Nepal, a decision on the merits may be a distant prospect.

A further set of challenges draws from the procedural and jurisdictional requirements of many judicial systems and the characteristics often associated with victims of right to food

violations. Many judicial systems contain complex procedural and jurisdictional requirements for bringing litigations such as requirements for standing (finding individuals or groups who may legally bring an action) or timing (bringing an action that is neither moot nor ripe). Some countries have addressed standing challenges by allowing public interest standing, whereby an entity can represent a population who may be unable to bring a case on their own. For example, the People's Union for Civil Liberties in India relied on a public interest standing provision in order to represent communities in Rajasthan and later food-insecure populations across the country. With respect to timing, different countries allow actions to be brought preemptively before a violation has occurred, during a violation, and after a violation.

A third set of challenges relates to the commonly held view that economic and social rights, including the right to food, are not justiciable and not enforceable by courts. The basis of this belief is multifaceted stemming from both a concern towards the cost and complexity of enforcing economic and social rights and a respect of the separation of powers. Implementing economic and social rights, as opposed to civil and political rights (the right to vote, the right to a fair trial, etc.), is seen as complex and costly because the rights require a redistribution of resources as well as the establishment of infrastructure or social programming to deliver the resources. This leads to more complex laws and a more expansive state (Kelley 1998; Neier 2006). Drawing from this, economic and social rights are viewed as non-justiciable, with courts being the improper venue to adjudicate violations because of the traditional separation of powers. Courts do not have the power of the purse and are not afforded law-making abilities. Allowing courts to adjudicate and make decisions with major financial and infrastructural consequences is viewed as an encroachment on the other branches of government, in particular the legislature. A recent court in Canada expressed such concerns when it found that economic rights, and in particular the right to housing, were not justiciable and that no protection for economic rights could be read into the Canadian *Charter of Rights and Freedoms* (Tanudjaja v. Attorney General (Canada) 2013).

National Courts in the Future

Despite the critiques and challenges to bringing right to food cases, national courts around the world are increasingly hearing and deciding cases on the right to food. As more countries adopt framework laws and constitutional protection of the right to food, or interpret the right to life as including a right to adequate food, more litigants may be able to bring right to food cases to court.

Changing understandings of the scope and reach of human rights law may also expand the role of national courts in the protection and promotion of the right to food in the future. For example, increased attention on the human rights obligations of businesses may lead litigants to challenge the actions of business enterprises on human rights grounds (Ruggie 2011). Similarly, a growing concern over violations of extraterritorial human rights obligations may lead to foreign litigants challenging government action in national courts as a result of violations committed abroad (Maastricht Principles 2012).

What role courts will play in the protection of the right to food in the future will depend on the ability of litigants to access courts, the availability of enforceable law for the judiciary to rely on, and the openness of the judiciary to engage in economic and social rights. The experiences of domestic courts to date illustrate that courts can be powerful actors in the fight against hunger, but that their role could be expanded. With the proper tools, courts could play an even greater role in protecting and promoting the right to food and serve as a source of redress for individuals whose rights have been violated.

Summary

National courts can play a key role in the advancement of the right to food by ensuring the right to food is upheld and through providing redress to individuals whose rights have been violated. Right to food litigation is still a relatively new phenomenon, with few domestic courts around the globe having expounded upon its tenets or made findings of violations. Nevertheless, there have been cases where litigants have claimed

violations of the right to food and where courts have made significant rulings on this most fundamental human right. This entry outlines the content of the right to food, the role national courts can play in implementing and enforcing the right to food, and what courts have done up to date.

Introduction

In April 2012, a picture of a note posted in a natural food store in Rhode Island went viral. It stated that Kashi cereals were taken off the shelves because they were made with genetically modified ingredients. For many customers, the use of genetically modified soy was incompatible with the company's "natural" labeling, but Kashi argued they had not done anything wrong. As a spokesperson explained, "the company defines natural as 'food that's minimally processed, made with no artificial colors, flavors, preservatives or sweeteners.'"

This case highlights the confusion around the concept of natural food. The *Codex Alimentarius*, established by the International Food and Agriculture Organization and the World Health Organization, includes no principles or guidelines for the production and labeling of natural food (World Health Organization and Food and Agriculture Organization of the United Nations 2013). Many countries have nonetheless developed their own definitions of the term "natural" as it applies to food. In the United Kingdom, for instance, the Food Standards Agency restricts the use of the label "natural" to foods that have "ingredients produced by nature, not the work of man or interfered with by man" (Food Standards Agency 2008). In Canada, the *processes* involved are what matters; the Canadian Food Inspection Agency (CFIA) states that food products should not be described as natural if they were "submitted to processes that have significantly altered their original physical, chemical, or biological state." CFIA goes on to give a list of processes affecting the natural character of food (Canadian Food Inspection Agency 2012, section 4.7). In the United States, the Food and Drug Administration (FDA) does not restrict the use of the term "natural," but discourages the food industry from using it. It is interesting to note that after beginning a process of trying to define the term in 1991, the FDA finally gave up in 1993 (Houchins 2008).

Kashi's case is not unique. Using the claim that some food is "natural" or "all natural" as a selling point is widespread in food marketing today. The success of the "natural" label as a marketing tool

suggests that many customers are looking to eat food that is – at least in some sense – natural and that they consider that food labeled as such is somehow better than the food they deem “unnatural.” A survey conducted among 1,006 US customers even shows that American customers do believe that a “natural” label is greener than “organic” (Scott-Thomas 2009). As the confusion around it shows, the term “natural” is a polysemous one. In his book *Keywords*, Raymond Williams (1985, p. 219) notes that “[n]ature is perhaps the most complex word in the language,” and long before him, Hume (1978, p. 474) famously said of the word “nature” that “there is none more ambiguous and equivocal.” This equivocality of “nature” makes it uneasy to clearly understand statements about the value-adding character of naturalness. This entry examines the various meanings of “natural” and their possible relevance for food ethics.

Natural, Supernatural, Artificial

A classical examination of the meaning of “natural” and its ethical relevance can be found in J. S. Mill’s essay “On Nature” (Mill 1874). In this essay, Mill isolates two meanings of “natural.” A first meaning, which will be referred to as **natural₁**, denotes “the sum of all phenomena, together with the causes which produce them; including not only all that happens, but all that is capable of happening; the unused capabilities of causes being as much a part of the idea of Nature as those which take effect” (Mill 1874, p. 5). This concept includes as natural all that happens in the physical world and thus defines “nature” as opposed to the *supernatural* or the *miraculous*. In a second sense, which will be called **natural₂**, “natural” means “what takes place without the agency, or without the voluntary and intentional agency, of man” (Mill 1874, p. 8). In this second sense, *natural* is opposed to *artificial*, understood as *human-made*.

In the context of natural food, **natural₁** is an obviously trivial concept, as food production cannot escape the laws of physics and make use of *supernatural* powers. **Natural₁** is presumably the

concept involved in most empty and deceitful claims of naturalness, such as those assigning an “all natural” label to highly processed food, like Frito-Lay’s line of “natural” potato chips or “natural” white cheddar *Cheetos*.

Natural₂, by defining naturalness in opposition to human intervention, seems, at first sight, to be a more plausible value-adding concept of naturalness. It can be seen for instance on the packaging of juices containing “only fruits.” “Natural food” is colloquially opposed to “processed food,” and here the epithet “processed” points intuitively to some technological transformation operated by humans. However, given the fact that almost all food consumed today is somehow human transformed and that many ingredients would not be comestible prior to undergoing at least some basic processing (e.g., chopping, mixing, centrifugation, deboning, or cooking), the concept of **natural₂**, if it is understood as an *all-or-nothing* affair, risks casting the net of natural food on a too-restrictive class of products. Even raw fruits like oranges, which often remain green when they are ripe, are exposed to ethylene gas to make them orange and saleable. Under an *all-or-nothing* interpretation, perhaps only berries self-picked in the wild would count as natural food. But as Siipi (2008, pp. 77–8) remarks, **natural₂** need not be so restrictively construed and can also be interpreted as a *continuous gradient*. In such an interpretation, food can be more or less natural according to the *amount* of human transformation involved in its preparation. Therefore, it seems that **natural₂** must be understood in this later way if it is to be applied to food in a practical way. There is a significantly different degree of transformation involved in, on the one hand, transformations that are usually not taken to destroy the naturalness of a product (e.g., grinding wheat and cutting up and cooking meat) and those involved in, on the other hand, the production of industrially processed food (e.g., hydrogenation, interesterification). Thus, **naturalness₂** interpreted as a *continuous gradient* seems better able than **natural₁** and the *all-or-nothing* **natural₂** to account for the distinction between natural and processed food by those who assign value to food in virtue of its naturalness.

A problem that remains with the continuous gradient **natural₂** concept, however, is that it appears to involve some level of arbitrariness. A first kind of arbitrariness comes from the fact that, as all other gradient notions when used for classificatory purposes, it faces a *threshold problem*. Provided that one could develop an uncontroversial way to quantify the degree of naturalness of a product (and this is far from being achieved), one would still have to establish a threshold above which some food is too human transformed to be legitimately labeled “natural.” As the continuous gradient of **naturalness₂** logically cannot, by itself, provide grounds to establish it, such a threshold would have to be set in reference to a property other than naturalness (say, the property of being the result of *industrial* transformations). Yet it follows then that this other property would have to be defined with some precision, and, to avoid circularity, this definition would have to avoid any reference to naturalness. In this case, however, the products under the established threshold of naturalness would be established as more desirable not in virtue of their **naturalness₂** *per se*, but in virtue of this other property by which the threshold is set.

Another, and perhaps more profound, way in which the **natural₂** involves arbitrariness is that, by defining naturalness in opposition to human agency, it implicitly sets humans outside of nature. This is arbitrary because it is widely accepted, and has been since Darwin first voiced his theory, that humans are the product of the same evolutionary processes as all other living beings, and that there can only be differences of *degree* between what human and nonhuman living beings do (Callicott 1991, pp. 349–50; Vogel 2003, p. 152). In this context, it is arbitrary to draw a special class with the outcomes of human activities. One could withstand this upshot by putting forward that human activity is significantly different from what other living beings do, because we humans are cultural beings, and this allows us to have incomparably more dramatic impacts on our environment than those of other animals. This response seems plausible, as although, like humans, other species significantly modify their environments (Ereshefsky 2007, p. 60; Jones et al.

1994) and transmit knowledge culturally (Ereshefsky 2007, pp. 65–6; Callicott 1991, p. 351), it seems correct to assert that *Homo sapiens* are unrivaled in the *degree* of these modifications. As Callicott (1991, p. 351) notes, it seems reasonable to concede that “the cultural component in human behavior is so greatly developed as to have become more a difference of kind than of degree.” As many ecologists have remarked (e.g., Angermeier 2000), this degree of cultural sophistication is what allows humans to have extraordinarily destructive impacts on the earth’s ecosystems; the changes brought in the ecological world are so wide in scale that other species cannot evolve quickly enough to adapt to them. Similarly in the context of food and human health, one could argue that, given humans’ ability to synthesize artificial molecules, our species is a lot more likely to produce molecules that cause health and ecological problems (like many of the chemical pesticides widely used in agriculture).

But should these observations be right, they would not support the claim that the potentially harmful effects of human’s cultural abilities are such in virtue of their being the effect of human culture *per se*. The fact that our cultural abilities *can* generate harmful effects does not imply that they *must*. On the contrary, the very fact that humans are cultural beings is what makes it (in theory) possible for us to learn from our mistakes and create more innocuous alternatives to our unsafe products. Thus, it seems that harmful unnatural₂ products are not to be disvalued because of their **unnaturalness₂** itself, but rather because of their harmfulness. Hence, given the fact that there is no *necessary* connection between ecological or health harmfulness and the concept of **naturalness₂**, the human/nature dualism presupposed by this concept seems to remain arbitrary.

Naturalness, Biological Normality, and Processed Foods

If customers were shocked by Kashi’s products, it is not because there is human agency involved in the production of those cereals. It is because they

contained genetically modified soy. What is so special about genetic modification?

For ancient philosophers, “nature” was conceptually tied to *life*, as indicated by the etymology of the Latin word “*natura*,” which means “birth,” and its Greek equivalent “*physis*,” which means “growth.” In accordance with this etymology, Aristotle used “nature” principally to denote the inherent principle of growth and development of living beings. He viewed living beings as having their own teleological or goal-directed tendencies, and these tendencies explained their usual forms and directions of growth in terms of what is *natural* for them to do. As historians have observed, these teleological tendencies engendered *rules* regulating the typical behavior of natural entities. These rules admitted exceptions but stood *for the most part or the most often* (Daston and Park 1998, p. 120).

The possibility of exceptions to the rules of nature allowed Aristotelians to define a concept of naturalness which is different from Mill’s **nature₁** and **nature₂**. For them, “natural” meant what happens according to the *normal* rules determining the functioning of complexly organized entities (resulting from their *telos*), and “unnatural” referred to breaches of these rules. The paradigm case of unnaturalness in this Aristotelian sense was that of *monsters*. For Aristotle, monsters were unnatural neither in the sense of *super-natural* (**unnatural₁**) nor in that of *human-made* (**unnatural₂**), but in the sense that they were deviations from the normal course of biological nature. This characterization indicates a third concept of naturalness: the **natural₃**, which can be defined as what happens according to the normal or ordinary course of the organic world. It is distinct from **natural₁** in that this latter concept is tied to matter and its necessary laws (the basic laws of physics), whereas **natural₃** relates to nature as organized into forms and its rules of normal functioning. It also differs from **nature₂** in that it is not opposed in principle to human agency, for deviations from the normal course of organic nature can occur with or without human intervention.

Nowadays, a similar idea of breach of the ordinary course of biological nature seems

involved in people’s repugnance for highly processed food, sometimes referred to as the “yuk factor” (Midgley 2000; Siipi 2008, pp. 91–2). Yuk factor events are not reactions to the mere fact that some products are human-made (i.e., that they are **unnatural₂**). Processed foods are perceived as artificial in the much deeper sense that they involve types of transformations or modifications which seem to lie outside the normal course of biological nature. For instance, if chemicals are added in food products to make them grow faster, be less prone to damage caused by insects or fungi, or simply to look better and last longer, when the chemicals used are not part of the normal biological processes characterizing the life cycle of these products, they will be viewed as less **natural₃**. A study by Rozin (2005) illustrates people’s intuitive use of a concept of **naturalness₃** in the evaluation of the naturalness of a product. The study shows that the perceived decrease of naturalness is stronger in the case of *chemical* transformations than in the case of *physical* transformations. “Physical transformation” in Rozin’s study denotes changes that do not alter the inner properties of the products involved, e.g., freezing water, grinding peanuts, or squeezing oranges, whereas “chemical change” denotes the opposite, e.g., boiling water, adding fat to peanut butter, pasteurizing, or irradiating milk. Such perception points to a distinction between, on the one hand, **natural₃** changes, that is, changes that do not alter the inner natures of the substances and entities involved, and which could happen through the normal course of the organic world, and, on the other hand, **unnatural₃** transformations, that is, alterations that denature the substances and entities involved by exposing them to processes of change that do not normally occur in the organic world. The legal definitions of “natural food,” in terms of processes mentioned at the beginning of this entry, also seem to involve such an opposition between chemical and physical processes of transformation.

Attfield (2006) defends the relevance of the **natural₃** for health-related issues. He argues that

[T]he *good* and equally the *harm* of a living organism depend on its nature. If we did not know the nature of an organism, we could not tell what

constituted its good or its harm. This is not just to say that the concepts of good and harm are species-specific; it is to say (unsurprisingly enough) that grasping the good or harm of a creature involves some grasp of its inherited constitution or make-up. (Attfield 2006, p. 111)

Attfield's contentions seem plausible. It appears reasonable to say that it is good, at least *prima facie*, for a being to grow and develop according to its nature. The standards of health for a living being depend on the kind of being it is; and as pain has plausibly evolved as a means to motivate animals to move away from things that threaten their life and health, it seems reasonable to think that, even for animals, there is a strong correlation between their well-being and what concurs with their natures. One possibly problematic case, however, is that of organisms of highly modified species (modified either through selective breeding or genetic engineering). If, in order to maximize profit, the genetic form of a species is selected in a way that it makes it painful for its members to grow according to their (human-modified) **nature₃**, then the correlation between **naturalness₃** and well-being disappears. For instance, in the previous 40 years, milk yield per dairy cow has more than doubled due to genetic selection. As a result, declining fertility, increasing leg and metabolic problems, and declining longevity have been observed. These are for the most part attributable to selection for increased milk yield and indicate a substantial deterioration in cow welfare (Oltenacu and Broom 2010). Today's dairy cows, then, are victims of their own **natural₃** growth processes, with individual cows prone to suffering without any further outside human interference.

From the perspective of the human food consumer, it may be healthier to eat **natural₃** food. Food whose production and conservation has involved significant chemical interference to normal biological processes is likely to be more harmful to health, if, as it often revealed to be the case, the chemicals involved have significant levels of toxicity for humans. However, if the chemicals involved kill some germs that are pathogens for humans, then their consumption will presumably be healthier than that of **natural₃**

food products. Hence, there might be trade-offs involved when assessing the relation between **naturalness₃** and human health. One could nevertheless argue that, in general, given that the dangers related to **natural₃** food are easier to assess and predict than those of foods with chemical additives, in the absence of contrary information, **natural₃** food should be preferred. The harmful effects of biological pathogens are usually observable quickly enough after consumption so that a correlation can be drawn between them and their harmful effects. This is not the case with the harms related to chemical additives, which are less easily tractable and sometimes become visible only long after someone has been exposed to them. For instance, exposure to pesticides is an important environmental risk factor associated with cancer development, but its effects can appear years after exposure.

What about the case of GMOs? Genetically modified organisms, sometimes denigrated as "frankenfoods" by their detractors, are often said to be unnatural because they "cross the species barrier." This idea of a "species barrier" seems to resonate well with the **nature₃** concept, as this concept is tied to the Aristotelian idea that species have essences which define their identity. Evolutionary biology, however, imposes qualifications to such idea. As it has been emphasized by biologists and philosophers of biology (Sober 1980; Mayr 1959), this sort of essentialist thinking about species is disqualified by evolutionary biology. According to Darwinian biology, species are not eternal essences, but concrete lineages in a perpetually ongoing process of change. Hence, in a Darwinian biological world, there are no sharp species barriers, and in this context, the argument that GMOs are unnatural because they cross such barrier is a nonstarter. Thus, if one wants to make the argument that GMOs are **unnatural₃**, one should point to other sorts of deviations from the normal course of the biological world involved in genetic engineering.

A counterargument to the idea that GMOs are unnatural is the picture of genetic engineering as simply an alternative way to achieve what evolution does all the time: creating and selecting biological variation. According to this line of

reasoning, genetic engineering involves nothing significantly different from artificial selection through repeated crossbreeding, a practice presumably as old as farming itself; and crossbreeding is itself equivalent to natural selection, as both use essentially the same processes (the selective pressures being the preferences of the breeder in the case of crossbreeding). But some would disagree with the view that there is no significant difference between genetic engineering and selective crossbreeding. In a biologically well-informed discussion of genetic engineering, Vandana Shiva (2000, p. 13) emphasizes important differences between the two practices: “[u]nlike conventional breeding, genetic engineering recombines genetic material from different unrelated species which do not interbreed in nature and for which there is no, or very little, probability of natural progeny.” As she illustrates, “conventional breeding does not transfer genes from bacteria and animals to plants. It does not put fish genes into potatoes or scorpion genes into cabbage. It crosses rice with rice, and wheat with wheat.” Hence, Shiva identifies ways in which genetic engineering achieves changes that could not occur normally in the biological world. Traditional crossbreeding faces the exact same constraints as natural reproduction, while the technique of recombinant DNA allows GMO producers to get around these constraints and achieve genetic combinations which could not occur through normal evolutionary processes. GMO plants like the soy contained in Kashi cereals are now commonplace illustrations of such combinations, but research is currently being done on genetically modified animal products (though none are on the market yet). One is the AquAdvantage salmon, an Atlantic salmon in which genes from a Pacific Chinook salmon and an ocean pout have been added in order to make it grow year-round and for the fish to reach market size in half of the time required for its non-modified counterpart (16–18 months rather than 3 years). Some modifications also involve human genetic material. In order to produce an alternative to infant formula, which is often criticized as being an inferior substitute to human breast milk, Chinese scientists have recently introduced

human genes into 300 dairy cows to give their milk the same properties as human mother’s milk.

Thus, although the “species barrier” argument is problematic in the light of Darwinian biology, there may still be good reasons to categorize GMOs as **unnatural**₃.

Ecological Naturalness

Daston (2010) distinguishes two versions of naturalness as biologically normal: *specific* natures and *local* natures. *Specific* natures refer to the essences or the kinds of entities, that is, “to what makes an object be itself, in a recognizable and distinct way, to its ontological identity card: what makes gold is gold (and not copper for instance), what makes a bear is a bear (and not a trout).” This version of the natural as the biologically normal is the Aristotelian one, which was the focus of the previous section, and sets the standard of normality at the level of the living organism. The other version of naturalness as the biologically normal depicted by Daston is that of *local* natures. As she defines them, the local natures are the “characteristic combination of the flora and fauna, of the climate and geology which confer a landscape its physiognomy: the desert oasis, the tropical forest, the Mediterranean coast or the heights of the rocky mountains” (Daston 2010, pp. 248–9). Daston adds that “[t]he modern science of ecology studies the way in which organisms and topography interact to create the distinct local natures; but the order of local natures was noticed long before the birth of this science” (Daston 2010, p. 249). According to this concept, “nature” refers to “the ecological world,” and “natural” denotes what is in harmony with the ecological world, or, in more technical terms, what promotes, or at least is not detrimental, to what some ecologists call ecosystem health (Dussault *in prep.*). This ecological concept forms a fourth concept of naturalness which will be referred to as **natural**₄.

The intuitive idea that the ecological world has an inherent balance which human industrial activities often upset is central to ecocentric views in environmental ethics (Leopold 1949; Callicott 1989, 1999), although it has been observed that

the idea of a *balance of nature* may require qualifications (Callicott 1999, 2003; Botkin 1990). According to such views, some food production practices may be deemed unnatural in the sense of unecological (**unnatural₄**). A study by Verhoog et al. (2003) illustrates the intuitive appeal to a concept of **natural₄** made by organic farmers and organic food customers in their characterization of organic farming as more natural than industrial farming. The respondents in Verhoog et al.'s study said that it was necessary to view nature not "as a mechanistic material system but as a complex organic living whole" which has "a self-organizing capacity." Moreover, although the respondents "[a]ll realized that farming as such is a cultural activity in which human beings interfere in nature," they nevertheless thought that somehow organic farming is "harmoniously integrated into nature," while conventional farming is not (Verhoog et al. 2003, pp. 35–8). The respondents' acknowledgement that farming is a cultural activity shows that the concept of naturalness they have in mind is not the **natural₂**, which excludes in principle humans' cultural activities; and their depiction of human interventions in nature as more or less in harmony with it clearly suggests a concept of ecological naturalness.

Just like the concept of **naturalness₃** had immediate connections with the issue of human and animal health, the concept of ecological naturalness is directly tied to ecological issues. As this concept is defined as what is harmonious with the healthy functioning of ecological systems, what is natural in this sense should be expected to be good from an ecological standpoint. However, substantive questions remain about whether particular food production techniques, such as irrigation or the use of GMOs, are (un)natural in this sense. Is irrigation ecologically equivalent to rain (presumably a **natural₄** phenomenon)? Are GMOs always a threat to ecosystems? The complexity of ecological dynamics implies that giving definite answers to such questions an uneasy task. Nevertheless, some clearer answers can be found when one considers how these food production practices are *currently* implemented. Irrigation plays a crucial role in increasing crop yields and stabilizing production but also causes major

environmental problems (Dougherty and Hall 1995). Meanwhile, GMOs initially supposed to free agriculture from chemicals are in fact used to bolster the chemical industry (Food and Water Watch 2013; Shiva 2000).

The connection between ecological naturalness and human and animal well-being issues is less straightforward. As humans and nonhuman animals can only thrive in healthy ecosystems, the goals of human and nonhuman well-being and that of ecosystem health seem to meet in the long term, but whether there are trade-offs between them in the short term remains an open question. Organic farming has been criticized as requiring more land to produce less food than conventional methods. The green revolution has contributed to a reduction in hunger in Asia; between 1970 and 1975, cereal production doubled, while land under cultivation only grew by 4%. Can organic farming feed the world? There is no clear consensus on this question (McWilliams 2009, pp. 55–61). According to a recent meta-analysis of 66 studies presenting comparisons of organic vs. conventional agriculture yields (Seufert et al. 2012), organic agriculture yields are typically lower than those of conventional agriculture, but these differences vary depending on the system and site characteristics and on the types of plants grown. The study reveals large organic vs. conventional yield differences for cereals and vegetables (–26% and –33%, respectively) and small ones for fruits and oil seeds (–23% and –11%, respectively). The study also observes that organic and conventional yields are more equal when best organic management practices are used (–13%) and when organic legumes or perennials are grown on weak-acidic to weak-alkaline soils, in rain-fed conditions (–6%).

One final observation about the concept of ecological naturalness concerns its relationship to **naturalness₃**. It may seem intuitive to suppose that if some food production involves a great deal of chemical transformation – thereby making it **unnatural₃** – this will also make it unnatural in the ecological sense. Some remarks by Odum (1971) on how ecological science should inform our food production practices, however, suggest

that processed foods may sometimes be natural in the ecological sense:

Present agricultural strategy is based on selection for rapid growth and edibility in food plants, which, of course, make them vulnerable to attack by insects and disease. Consequently, the more we select for succulence and growth, the more effort we must invest in the chemical control of pests; this effort, in turn, increases the likelihood of our poisoning useful organisms, not to mention ourselves. Why not also practice the reverse strategy – that is, select plants that are essentially unpalatable, or that produce their own systemic insecticides while they are growing, and then convert the net production into edible products by microbial and chemical enrichment in food factories? We could then devote our biochemical genius to the enrichment process instead of fouling up our living space with chemical poisons! (Odum 1971, p. 269)

The first “Frankenburger,” made from lab-grown meat and consisting of stem cells that were placed in a medium to grow and reproduce and then bound together by Prof. Mark Post’s team in Maastricht, was recently served at a press conference in London. Compared with conventionally raised livestock, large-scale production of cultured meat would reduce water, land, and energy use, as well as emissions of greenhouse gases. In vitro meat production may also decrease contamination with bacteria like *Salmonella* and *E. coli*, by eliminating contact with animal feces.

Another possible point of divergence between the **natural₃** and the **natural₄** concerns the debate over the (un)naturalness of vegetarianism. Usually, this debate centers around the question of whether our species has evolved to be herbivorous or omnivorous. This is a question about the **naturalness₃** of vegetarianism, that is, about the evolved normal capabilities of our species’ digestive organs. From an ecological standpoint, however, what past evolution has made us physiologically capable of should not dictate what should or must be done. What matters in this case is what our species must *now* do to live in harmony its supporting ecosystems. It has been clearly shown that the earth’s ecosystems will not be able to support the growing human population if we all eat meat (McMichael et al. 2007). Thus, insofar as we are able to live healthy lives on vegetarian diets, doing so may well be what is ecologically natural

(**natural₄**) for us to do. This is indeed why ecocentrists like Callicott (2002) have emphasized the ecological reasons for vegetarianism:

Much of the plow land in midwestern United States is devoted to feed crops, such as corn and soybeans, most of which are eaten not by human beings, but fed to factory farmed cows, pigs and chickens. Animals burn about 90 percent of the food they eat and convert the rest (only 10 percent at best) to meat, so Americans would need only about 10 percent of the land now under cultivation to grow food if we consumed grains and legumes directly and altogether eliminated mass-produced meat from our diets. The elimination of industrial animal agriculture would, therefore, make millions of acres available for prairie restoration on a truly grand scale. (Callicott 2002, p. 319)

Summary

Four concepts of naturalness have been defined and discussed:

Natural₁: What happens according to the basic laws of physics? Natural as opposed to *super-natural* or *miraculous*.

Natural₂: What happens independently of human voluntary agency? Natural as opposed to *artificial* or *human-made*.

Natural₃: What happens according to the normal or ordinary course of the organic world? Natural as opposed to the *monstrous* or *biologically abnormal*.

Natural₄: What stands in harmony with the ecological world? Natural as opposed to *unecological* or *ecologically harmful*.

Natural₁ includes anything physically possible and so fails to draw a useful distinction between natural and unnatural foods. **Natural₂** seems at first sight to capture the intuitive natural/unnatural food distinction, but reveals problematic upon closer analysis for three main reasons: (1) It sets humans outside of nature when doing so is incompatible with Darwinian biology; (2) it is too restrictive when understood as an *all-or-nothing* affair, as almost all sorts of food involve human transformations, and (3) it faces a problem of threshold arbitrariness when

understood as a *continuous gradient*. **Natural₃**, by drawing a distinction between biologically normal and abnormal processes, seems better suited to account for the intuition that highly processed and genetically engineered food is unnatural, and to justify, to some extent, the intuition that natural food is usually safer and healthier. **Natural₄** resonates with the common observation that some food production practices like organic farming are more natural in the sense that they are in better harmony with and less harmful to the ecological world.

This classification confirms the polysemous character of the term “natural” but at the same time reveals that this polysemy does not preclude the notion from being helpful in discussions of food ethics. Two concepts of naturalness, **natural₃** and **natural₄**, have been shown to have some relevance for issues central to this field, like animal welfare, human health, and environmental ethics. Indeed, many particular questions about the value of natural food remain when looking at specific issues discussed in those fields.

Introduction

The Neolithic Revolution was a process of transition from a nomadic lifestyle of hunter-gatherer communities to one of agriculture and pastoralism, as well as the start of a sedentary lifestyle. This transition took place at a varying pace in different regions of the world. It is assumed that the major proportion of the human population underwent this process in the period between 10,500 and 6,000 years ago. The Neolithic Revolution was a consequence of a transition from gathering food, which was typical of pre-agrarian societies, to food production, which is observed in agricultural societies. It was accompanied by fundamental changes, which were characteristic of the whole process, such as development of sedentary village life, growth in population, use of ground-stone tools, development of ceramics, and the emergence of a new type of social organization.

The crucial factor which contributed to the advent of the Neolithic Revolution was the invention of agriculture, since it allowed humans to satisfy basic needs in a permanent and stable way. To understand the complex civilizational processes taking place in the framework of the Neolithic Revolution, it is necessary to understand the role played in this process by so-called domestication.

The term is usually referred to as, “a sustained multi-generational, mutualistic relationship in which one organism assumes a significant degree of influence over the reproduction and care of another organism in order to secure a more predictable supply of a resource of interest, and through which the partner organism gains advantage over individuals that remain outside this relationship, thereby benefitting and often increasing the fitness of both the domesticator and the target domesticate” (Zeder 2015).

This process takes place between the two poles designated as “wild” and “domestic.” Consequently, one can talk about various stages or levels of domestication, which are dependent on the scope of the influence exerted by environmental, biological, and cultural factors. These factors can have either a rapid or a gradual impact on the

living organisms. Animal domestication provides an excellent example of the latter type of domestication, as it consists of a number of clearly discernible intermediate stages. At the initial, “wild” stage of domestication, a given population of organisms generally has no experience of any direct or indirect impact on the part of man. Domestication ends at the “domestic” stage, when a given population is totally dependent on humans with regard to such issues as survival, reproduction, and nutrition.

In the case of plant domestication, depending on the means used by man, the process can be divided into several stages:

1. Unconscious selection of plants for desirable traits, by 8,500 BC
2. Conscious cultivation of plants with desired traits, about 10,500 years ago
3. Deliberate breeding to improve traits, in the eighteenth century
4. Scientific breeding: genetic mechanisms known and exploited, at the beginning of the twentieth century, and
5. Direct genetic manipulation, from the twentieth to the twenty-first century

Despite numerous studies in this area, it is still impossible to provide a precise answer to the questions of how, where, and when plant domestication, which initiated the development of agriculture, was practiced by humans for the first time. In the last few decades, interdisciplinary research, conducted by botanists, geographers, archaeologists, anthropologists, and environmental historians have provided information that allows us to clear up at least some doubt on the origin of agriculture. These studies illustrate the impact that agriculture exerted on both the environment and the life of human communities (Bellwood 2005).

A popular stereotype often equates domestication and taming. However, it is important to differentiate between the two concepts. Taming is usually defined as the conditioned behavioral modification of a wild-born animal, when its natural avoidance of humans becomes reduced and it accepts the presence of humans. Domestication is a permanent genetic modification of a bred

lineage that leads to an inherited predisposition toward humans.

In order to provide a truthful picture of the Neolithic Revolution, it is necessary to sketch phenomena such as agricultural transition, or plant and animal domestication, and discuss the influence of the Neolithic Revolution on human communities, i.e., social, medical, and technological consequences.

Agricultural Transition

The conducted research does not allow us to specify either the area or the date of transition from gathering to producing food for the first time. Most probably, it was a gradual process. Hunter-gatherer communities began to increase their economic reliance on the production of food, gradually turning into agricultural communities. It appears that, for a long time, people gathered the grains of wild cereals, which constituted a significant component of their diet. Most likely, however, the first domestication of plants did not take place before approximately 8,500 years BC, while domestication of animals not before approximately 8,000 years BC. There are also many indications that food production began at different times in different areas. In some cases, food production was initiated as a result of independent discoveries, while in other, from borrowings from neighboring societies (Cowan and Watson 2006).

In all probability, humans began to produce food for the first time in the valleys of two great Asian rivers, the Yellow River and the Yangtze River. Modern research can indicate with certainty five areas where the first domestication of plants took place (Diamond 1997):

1. Southwest Asia, also known as the Near East or the Fertile Crescent
2. China
3. Mesoamerica (the term is applied to central and southern Mexico and the areas adjacent to Central America)
4. The Andes of South America, and possibly the adjacent Amazon Basin, and
5. The Eastern United States

A number of scientific discoveries provide some evidence that early food production took place in four other areas of the world. Although that evidence is not as indisputable as in the case of the five areas mentioned above, nevertheless, it may be assumed that food production most likely took place also in:

1. Africa's Sahel zone
2. West Africa
3. Ethiopia, and
4. New Guinea

Scientists are generally unanimous as far as the beginnings of agriculture are concerned. It appears that land has been cultivated by humans for over 10,500 years. Naturally, this does not imply that 10,500 years ago land was cultivated all over the world, since at that time food production started only in selected areas. It is much more difficult to specify the genesis of agriculture than the date of its introduction. Scientists still differ in their views and, consequently, there are many hypotheses which attempt to explain why humans domesticated plants and animals and began to produce food.

Many indications suggest that agriculture developed gradually and was invented by chance while people collected the seeds of wild grains and other edible plants and disposed of non-edible plants growing close to edible plants to provide better conditions for their growth. Most likely, people noticed the dependence between the number of plants of a specific species and the amount of grain scattered on the occasion of their collection. The argument cannot be rejected that this was precisely the reason why humans began to sow seeds of desired plants, in this way hoping to receive larger quantities of food. Initially, however, human activity was limited in this regard only to more or less conscious spreading of grains and was not associated with any kind of concern for their growth.

As a result of numerous studies, scientists have presented a number of competing theories with the view of explaining the origin of agriculture. The most famous among those include the following (MacNeish 1992).

The Oasis Theory, which argues that the climate change that occurred in the late Pleistocene caused the expansion of desert areas in the Near East which, in turn, forced humans and many species of fauna and flora to cluster in a small area of a group of oases. Such concentration of many edible species of plants and animals meant that people began to experiment with them, and thus invented agriculture. This is one of the earliest theories and it was put forward by Raphael Pumpelly in 1908. Modern climate research, however, does confirm those assumptions but the theory does not have many supporters nowadays.

Hilly Flanks Theory postulates that the development of agriculture was a “logical outcome” of the evolutionary tendency to specialize. After gatherer communities settled at the end of Pleistocene, they gained better knowledge of the plants and animals living near their settlements. It helped to change the system of obtaining food from collection to production. According to this concept, humans noticed exceptional growth of the wild ancestors of today’s wheat and barley in certain locations, i.e., on the slopes of mountains in regions with frequent rainfall and characterized by favorable temperatures. Plants grew there without the need to provide them with water. However, modern research in the field of geomorphology and paleoclimatology does not confirm the theses raised by supporters and propagators of this theory, Robert Braidwood and V. Gordon Childe.

Feasting Model Theory is not as strictly connected with environmental factors as the two theories mentioned above, and it assigns the key role in the development of agriculture to cultural factors. This theory was presented by Bryan Hayden, who took the view that the origin of agriculture was inextricably associated with the exercise of power in primitive human societies. The leader of the community ostentatiously showed their dominance by systematically throwing feasts for the members of their community and this, in turn, required large amounts of food. According to this theory, the need for increased quantities of food

somehow forced gatherer communities to invent a new strategy of acquiring it, i.e., its production.

Domestication Theory argues that humans settled in particular areas, abandoning the gatherer-hunter strategy of acquiring food. Establishing annual or seasonal settlements, they were able to take care of the species living in the area. In this way, they gained food to satisfy their essential needs. This lifestyle led to the invention of agriculture. The theory of the origin of agriculture is supported by Daniel Quinn, among others.

Dump Heap Hypothesis assumes that people invented agriculture by chance, when they observed how the seeds of edible plants thrown on dump heaps grew into robust plants because of the abundance of nutrients available there. With time, those accidental “crops” induced humans to undertake deliberate and planned activities, which resulted in the invention of agriculture. It seems that this concept was initially supported by Theodor H. Engelbrecht and popularized by Edgar Anderson.

Marginal Habitat Hypothesis states that the climate change which took place at the end of Pleistocene led to the concentration of areas rich in resources, and this contributed to sedentarism and growth in the human population. Some human societies increased their numbers to such an extent that they had to use the areas which did not constitute an optimal environment for breeding plants and did not provide as much food as the more fertile areas. Consequently, people were forced to undertake some soil management practices in those marginal environments in order to increase the amount of the acquired food, which initiated the cultivation of crops. Supporters of this concept of the origins of agriculture include Lewis Binford, Kent Flannery, and David Harris.

Coevolution/Symbiotic Hypothesis states that food production was the outcome of a natural symbiotic relationship between humans and nature. Selection of plants did not take place as the result of human conscious decisions but was a by-product of the ways in which humans

used various species of flora and fauna. Supporters of this concept include, among others, David Rindos.

The theories presented above constitute just a few examples of explanations regarding the roots of agriculture. Each of the concepts provides arguments in its support and each attracts criticism. Due to the very limited knowledge regarding human life several thousand years ago, it is impossible to state with absolute certainty which of the concepts is true or to what extent it reflects the cause of the invention of agriculture. They all, however, provide a picture that illustrates the complexity of the problem and its multiple conditionings, due to which humans, through the Neolithic Revolution, entered a new stage of history.

Plant Domestication

The domestication of plants was a necessary condition for the Neolithic Revolution. Without its discovery, agriculture would not be possible at all. It is difficult to provide general information regarding the domestication of particular species of plants, i.e., dates and regions where it took place. Scientific publications usually present data on plant domestication relating to particular regions of the world (Price and Bar-Yosef 2011).

However, in retrospect, we can identify the species of domesticated plants that played the most important role in the development of human civilization. Most often, this group includes eight crops, which are defined as the “founder crops.” In all likelihood, plant domestication took place in the Fertile Crescent. Those species include emmer wheat, einkorn wheat, barley, lentil, pea, chickpea, bitter vetch, and flax (Zohary et al. 2012).

The difficulty in presenting the data on plant domestication consists of, among others, the fact that several species were domesticated independently in various parts of the world at different, sometimes distant, periods of time. As a result, it is sometimes difficult to define the time and region of the first domestication of a given species.

Table 1 presents general information on the domestication of selected plant species, indicating where and when the first confirmed domestication took place (Diamond 1997).

Animal Domestication

Animal domestication was a consequence of plant domestication, and it significantly contributed to the development of agriculture through the various ways in which the animals were used in the cultivation of land. As in the case of plant domestication, it is difficult to determine either

Neolithic Revolution, Table 1 Plant domestication

Area	Domesticated plants	Earliest attested date of domestication
Independent origins of domestication		
Southwest Asia	Wheat, pea, olive	8,500 BC
China	Rice, millet	by 7,500 BC
Mesoamerica	Corn, beans, squash	by 3,500 BC
Andes and Amazonia	Potato, manioc	by 3,500 BC
Eastern United States	Sunflower, goosefoot	2,500 BC
? Sahel	Sorghum, African rice	by 5,000 BC
? Tropical West Africa	African yams, oil palm	by 3,000 BC
? Ethiopia	Coffee, teff	?
? New Guinea	Sugar cane, banana	7,000 BC?
Local domestication following arrival of founder crops from elsewhere		
Western Europe	Poppy, oat	6,000 BC to 3,500 BC
Indus Valley	Sesame, eggplant	7,000 BC
Egypt	Sycamore fig, chufa	6,000 BC

the region or the date of first domestication in the case of particular species of animals, especially given that some of them were domesticated independently in different regions of the world. A good example of the difficulty in determining the place and time of domestication of some species is cattle, which were domesticated independently in India and in the western part of Eurasia during the last 10,000 years. In both regions, however, two different subspecies were domesticated that had originally diverged hundreds of thousands of years earlier.

In various regions of the world, humans domesticated numerous species of animals. Most of them were small mammals and birds. The biggest role in the Neolithic Revolution was played by domestication of big terrestrial herbivores (over 100 pounds). Until the nineteenth century, only 14 such species were successfully domesticated. Those species are usually divided into two groups.

The Major Five, five domesticated species that spread almost all over the world and played a major role in the development of human civilization: sheep, goat, pig, cattle, and horse.

The Minor Nine, nine domesticated animal species that live only in certain areas and played a significant role in the development of civilization in different regions: Arabian (one-humped) camel, Bactrian (two-humped) camel, llama and alpaca, donkey, reindeer, water buffalo, yak, Bali cattle, and mithan.

From among the 148 existing large herbivorous mammals, humans only managed to domesticate 14, of which as many as 12 occur in Eurasia and northern Africa. It seems that the most important factors with regard to some species of animals being successfully domesticated, while others were not, include diet, growth rate, breeding habits, disposition, temperament or tendency to panic, and sociability (Wallech et al. 2012).

Table 2 presents general information on the domestication of selected animal species, indicating where and when the first confirmed domestication took place (Diamond 1997).

Neolithic Revolution, Table 2 Animal domestication

Area	Domesticated animals	Earliest attested date of domestication
Southwest Asia	Sheep, goat	8,500 BC
China	Pig, silkworm	by 7,500 BC
Mesoamerica	Turkey	by 3,500 BC
Andes and Amazonia	Llama, guinea pig	by 3,500 BC
Eastern United States	None	?
? Sahel	Guinea fowl	by 5,000 BC
? Tropical West Africa	None	
? Ethiopia	None	
? New Guinea	None	
Western Europe	None	
Indus Valley	Humped cattle	7,000 BC
Egypt	Donkey, cat	6,000 BC

Consequences of the Neolithic Revolution

The Neolithic Revolution played a crucial role in the development of civilization. Its consequences for the progress of human societies cannot be overestimated. It seems that the changes induced by it were most visible in its social, medical, and technological consequences.

Social Consequences of the Neolithic Revolution

One of the consequences brought about by the Neolithic Revolution was a surplus of food, which had an impact on the growth in the human population and an increase in the number of individual human communities. This was possible due to the introduction of a sedentary or semi-sedentary lifestyle, forced by agriculture. The transition from a nomadic lifestyle of hunter-gatherers to a sedentary lifestyle of agriculturalists enabled people to raise more children. A nomadic lifestyle and the associated restrictions resulted in the fact that women in hunter-gatherers communities were only able to raise children at intervals of at least 4 years, while women in

agricultural communities could raise children at 2-year intervals (Diamond 1997).

The emergence of large communities meant the need for new types of leadership, which were not necessary in relatively small, egalitarian groups of hunter-gatherers. This development of governmental organization also brought about the emergence of a social elite, whose main role consisted of making decisions and managing the community. Developing agriculture led to the formation of social classes. Those groups later specialized in the production of food, manufacture of products, and trade of food and craft products, as well as defense and management of the community. One result of the phenomena initiated by the Neolithic Revolution was the establishment of the first cities and the first state structures.

Medical Consequences of the Neolithic Revolution

Besides the above-mentioned consequences, the Neolithic Revolution brought about another important effect, the appearance of so-called crowd diseases and the easier spread of infections. The development of densely populated, sedentary societies, in which people lived in close proximity with domesticated animals and in conditions of poor hygiene, gave rise to new types of zoonotic diseases (McCarter 2008). It was a new phenomenon, which had not occurred in hunter-gatherer communities. An increased density of population and the development of trade contacts were also conducive to the easier transmission of diseases, which constituted a serious threat to entire communities. Examples of zoonoses which appeared at that stage of development of civilization were influenza, smallpox, and measles (Karlen 1996).

Communities which first domesticated animals came into contact with new diseases and, consequently, were the first to build up immunities to the diseases. This was of great importance in the colonization of further areas. In the period of great discoveries, Europeans, who had long been immune to many diseases present in the Old World, passed those diseases onto the people of the New World, who were not resistant to new infections. This resulted in plagues that decimated

indigenous communities, sometimes resulting in a mortality of up to 90%. The transfer of Old World diseases to the colonized areas significantly contributed to the successful conquest of new lands by Europeans (Diamond 1997).

Technological Consequences of the Neolithic Revolution

The development of technology was another significant consequence of the Neolithic Revolution. The appearance of large human settlements gave rise to a social group engaged in the production of tools and other goods. The growing demand for better agricultural tools and weapons, as well as contacts among communities, enabled people to exchange their inventions and brought about systematic development of new technologies. The Neolithic Revolution contributed to the rapid and systematic technological development of human societies. This process began with the use of river floods and the burning of forests for cultivation, constructing ever more efficient tools and leading to the development of complex irrigation systems and the introduction of various land management techniques.

In the period between 7,000 and 4,000 years ago, the first stone and wood implements were used in the cultivation of land. The first primitive ploughs were used at least 5,000 years ago. Later, from 4,200 to 2,800 years ago, there is evidence of the first animal-drawn plough. Starting in the pre-Roman Iron Age (2,800 to 2,000 years ago) the ploughshare was reinforced with iron. In turn, the first irrigation systems were created, probably in Egypt, approximately 7,000 years ago. The Sumerians started building irrigation and drainage canals 5,000 years ago, in the Euphrates and Tigris region. Over time, they developed a technique to increase the fertility of the soil, which yielded smaller crops due to cultivation. This was achieved by means of prolonged fallow periods or by fertilization (organic and inorganic fertilizers). People also systematically worked on improving domesticated species of plants and animals through selective breeding of plants and line and cross breeding of animals (Martin and Sauerborn 2013).

Conclusion

The Neolithic Revolution is the first in the history of the human race which, due to a radical change in lifestyle, allowed for a systematic development of humankind. What is more, this revolutionary transition seems to have provided the foundations for the subsequent revolutions, which mark the further stages in the development of our civilization, i.e., the scientific revolution, industrial revolution, technological revolution, digital revolution, and nanotechnology revolution.

The unprecedented development of the human species was, however, only possible thanks to the Neolithic Revolution, during which humans abandoned the nomadic lifestyle of hunter-gatherers and adopted the sedentary lifestyle of farmers. Domestication of many species of plants and animals catalyzed the development of agriculture and allowed for the production of large surpluses of food. This, in turn, enabled a significant part of the human population to live in cities and create complex social and state structures. The emergence of specialized social groups contributed to technological development and cultural exchange due to lively contacts between communities.

The Neolithic Revolution, however, also had disastrous consequences for humans. The most conspicuous example here is the appearance of new diseases brought about by the domestication of animals and human residence in large population centers. The invention of new types of weapons allowed humans to eradicate many species of animals and exterminate many human communities. The Neolithic Revolution resulted in anthropogenic changes in the environment on a massive scale, which consequently led to the contemporary ecological crisis. It seems that a proper understanding of the processes initiated by the Neolithic Revolution and an in-depth reflection on the style of human presence in the world can raise hope that the threats faced nowadays by our planet may be identified and that it will enable us to develop strategies to overcome the ecological crisis.

Introduction

The food industry is far more complex today than it was even 20 years ago. The sheer magnitude of merchandise on the market and the amount of information available to both producers and consumers are unparalleled. This complexity poses challenges to scientists, marketing specialists, and others who research the impacts of the food industry on health and well-being. Increasingly, neuroscience has become an important research tool.

Food Industry and Neuro-medicine

There are different applications of neuroscience in the food industry. Neuroscience can be used, for example, to study how people with different deficits perceive food or how their perception determines their food intake. The health-related sphere of neuroscientific investigations concerns the role of food consumption in curing diseases or at least strengthening their symptoms. Another application is studying how the selection of food determines the condition of life among those suffering from cognitive impairments, multiple sclerosis, tumors, and other illnesses. Neuroscientists research the role of dietary choices as determinants of health conditions (Adan and Kaye 2011).

Another perspective taken in neuroscientific research is the focus on food as the core aspect in diseases. Researchers study neural circuits and neurotransmitters in food disorders, such as anorexia nervosa, bulimia, and overeating, looking at these issues through the prism of genetics or endocrinology (Adan and Kaye 2011). Neuroscientific research also focuses on the part of a brain responsible for eating disturbance to help people suffering from food disorders.

Another aspect of food interesting for neuroscientists is functional food. The studies focus on the way functional food keeps individuals in good health conditions or accompanies recovery processes after combatting illnesses. Some scientists also examine how food determines the condition and state of health among various individuals by showing the influence of alimentation on everyday activities, such as sleeping, learning, and exercising sport (Gomez-Pinilla 2008).

Another issue discussed by neuroscientists is how emotions determine food selection. They examine how individuals select food products when they face different situations and how their positive or negative attitudes determine what they eat and how much they eat. Since stress belongs to the reality of modern times and accompanies the life of individuals, the issue of how food selection changes under stress is taken into account. For example, stressed subjects opted more often for unhealthy high-caloric sweet products than the ones who were not stressed during the conducted

investigations. This study shows that stress increases the amount of consumption among stress-eaters, and, at the same time, the consumption is more concentrated on high-caloric food (Zellner et al. 2006). Such studies draw one's attention to the need of controlling the food intake when stressful situations occur.

Another group of investigations connected with neuroscience and food encompasses the role of food and other substances on brain functioning. They focus on how various food products alter different functions of one's brain. Such experiments show which products offered for drinking and eating influence one's cognitive abilities in positive or negative ways. Among others, researchers study how caffeine, vitamins, alcohol, and herbs determine the way brain performs in the short and long term as far as motor or cognitive functions are concerned (Zellner et al. 2006).

Scientists are also interested how agricultural pesticides, preservatives, or heavy metals in food products influence brain performance. The important correlation between nutrition and neuroscience has led to the creation of the domain called *nutritional neuroscience* that focuses on how the intake of food determines brain characteristics and performance, such as neurochemistry, neurobiology, cognitive and motor functions, etc. Neuroscience in these cases helps explain how consumption and the features of various food products, together with their components, shape individual behavior and health. It shows how vitamins, minerals, additives, and other substances determine brain performance. Its findings are useful in health and disease, to enhance proper nutrition and limit the spread of illnesses (Dauncey 2009).

The role of food on one's health is also studied from the perspective of agriculture. Taking into account the fact that many modern societies are aging, it becomes more and more important to take care about the cognitive abilities of the elderly by paying attention to proper nutrition. One of the ways to study the relation between food selection and cognitive abilities is to observe how certain products shape the cognition of individuals. For example, flavonoids affect memory as well as data storage in a positive way, by

limiting cognitive deterioration (Dixon and Pasinetti 2010). Thus, neuroscience and agriculture can merge their research achievements in advocating proper nutrition for those who are more likely to suffer from certain diseases. Those who already fight with some health problems can combat them by choosing products that may be beneficial for their cognition or mood. Neuroscience can also enhance studies in helping agriculture to offer agricultural products that will facilitate curing.

Food Industry and Neuromarketing

The popularity of neuroscientific theory in the area of marketing has led to the creation and development of neuromarketing. Neuromarketing is a new field of marketing that studies consumers' sensorimotor, cognitive, and affective response to marketing stimuli. Neuromarketing concentrates on the neuronal results of market-related strategies, with the purpose of understanding the processes taking place in the brain and, consequently, comprehending what customers wish and want (Peters and Ghadiri 2011). Or, taking a broader perspective, it can be perceived as understanding how the brain works and how employing knowledge on brain functions can stimulate marketing and product sales (Dooley 2012). This perspective offers a new way of studying how customers react to food and how their reaction shapes their selection of food products and their consumption. Since standard methods of research may involve some conscious manipulation of real data on the side of an interviewed subject (e.g., a person may provide fake answers), neuroscientific methods prove to be more reliable in some contexts. Neuroscience also provides information which part of the brain is responsible for which aspect of food selection (Roebuck 2011).

For example, neuromarketing examines the roles of the nucleus accumbens (the pleasure center), hippocampus (the memory center), frontal cortex (the decision center), and the visual system (the message selection center) (Georges and Badoc 2010). Neuromarketing researchers often concentrate on reward-related brain regions, such

as the nucleus accumbens and orbitofrontal cortex, since they are believed to mirror the choices made by consumers. For example, if a product causes a higher response in nucleus accumbens, it shows a subject's preference for the given merchandise. Neuromarketers also study how food selection is driven by emotions and how one's mood determines what one buys and eats. The popularity for the increasing interest in using neuromarketing for different disciplines of modern life, including the food industry, is connected with the possibility of analyzing the alimentation sector simultaneously from different perspectives (Haynes 2011).

Neuromarketing approaches can also be applied by taking into account a particular element of cognition investigated by researchers. Different senses, such as visual, auditory, olfactory, tactile and haptic ones, are important in studying individuals' behavior toward food products. Scientists can research how, for example, olfactics, haptics, or oculistics determine one's approach toward a given type of nourishment (Raab et al. 2009).

Neurolinguistics and the Food Industry

One of the most important issues shaping or accompanying customer behaviors is language. The interest of neuromarketers in the linguistic layer of food industry is often focused on linguistic branding that can be understood as examining how the names of brands determine customers' attitude to products and their choices, how individuals view and understand brands, and how they store brand-related concepts. The role of neuroscience in branding is crucial since the brain determines brand recognition (Bielenia-Grajewska 2013a). To show one aspect of the brain-brand relation, it should be remembered that one element of branding, such as a logo, engages 75 separate modalities of both hemispheres (Gordon 2006). Brands can be studied through the prism of perception. Taking into account the linguistic sphere, brand names are processed more quickly than no words, but more slowly than common words (Gontijo et al. 2002).

Another domain important for linguistic branding is phonology, for example, the interrelation between phonology and names. For example, neurolinguists are interested how the pronunciation of a food product determines purchasing behaviors. Neurolinguists also focus on paralinguistic elements of food communication. Paralanguage, composed of nonverbal elements of speech, such as intonation, pitch, or volume, is also crucial for the perception of food products. In addition, together with linguistic elements, paralanguage shapes the linguistic side of company identity. Another potential field of interest in neurolinguistics is the interrelation of verbal and nonverbal elements of communication, being represented in the color, size, or shape of fonts and their correlation with purchasing decisions.

Food communication from the perspective of neuroscience can be studied at different levels, such as micro, meso, and macro ones. As far as the microlevel is concerned, morphemes can be investigated and how such small linguistic elements as suffixes or prefixes determine the perception of food products. The analyses on the meso-level may encompass studies on the role of words used in product advertisements and their role in food choices. Discussing the methodological side of linguistic analyses and different types of linguistic tools used to create food-related discourse on the word level, symbolic language constitutes one of the most powerful instruments of the so-called stakeholder-producer/farmer communication. Among others, metaphors belong to very popular linguistic tools of discourse in the alimentation sector. They are used to create the identity of companies, by showing through organizational metaphors different characteristics of companies operating in the alimentation sector (Bielenia-Grajewska 2013b).

Another potential application of metaphors in the studied domain is the role of metaphors in the discourse of food-borne diseases. In this case, metaphors do not only mirror the features of diseases, but they also reflect the attitude of those affected by them. In this case, the selection of metaphors may increase or decrease individuals'

fear toward different food-borne diseases (Bielenia-Grajewska 2013c). Such studies may also facilitate the analysis of the way food stakeholders communicate and discover the tools that make their discourse more efficient. As far as the macro level is concerned, texts or speeches on alimentations and their influence on stakeholders can be analyzed.

Neuroscientific Techniques and the Food Industry

Those specializing in neuromarketing deal with neurophysiological tools such as the eye tracking, skin conductance, electroencephalography (EEG), and functional magnetic resonance imaging (fMRI) to conduct market-oriented research (Plassmann et al. 2012). One of the most popular tools in neuroscience is functional magnetic resonance imaging; it is a neuroimaging technique that relies on magnetic resonance to observe brain activities. The typical fMRI experiment is composed of various stages during which the subject is requested to lie still in an MRI scanner for about 60–90 min. The first 6–15 min are spent on making anatomical/structural scans of the brain. During the next parts of the observation (several series, 3–10 min each), the individual is asked to perform some activities. For example, a visual stimulus can be presented on a screen, and a subject can be asked to respond to a question by pressing the selected button. During the performance of tasks, the MRI scanner records the BOLD (blood oxygen level depending) signal every few seconds. This technique allows researchers to observe which brain areas are active and which are less active during the performed activities in comparison with the mentioned control scans (Kenning et al. 2007).

The selection of neuroscientific method is determined by different factors. One of them is the issue of costs connected with conducting neuromanagement experiments. Another important determinant is the notion of transporting neuroscientific equipment. Taking into account the criterion of portability, fMRI has to be used in a

special place because of its heaviness and other technical conditions that have to be observed during the usage of this equipment. The third factor is the notion of invasiveness. For example, individuals may not be willing to take part in invasive experiments that may involve some risk for their health. This opinion is also shared by many scientists who opt for noninvasive experiments to eliminate potential side effects among subjects (Bielenia-Grajewska 2013a).

Taking into account the medical dimension of studying food industry from the neuroscientific perspective, both invasive and noninvasive methods are used, depending on the purpose of studies and the state of patients. Preferences are, of course, directed at the noninvasiveness of research; however, there can occur a need to use an invasive method if the noninvasive tool proves to be not efficient. For example, positron emission tomography (PET) is used in diagnosing cancer and the influence of therapy in curing those affected by this illness; it is said to be more effective than other neuroscientific tools, such as magnetic resonance imaging. As far as the method itself is concerned, a patient is given a weak radioactive contrast agent that moves in the blood to the brain and concentrates in the areas having high metabolic activity that are visible on a screen (Raab et al. 2010).

Conclusion

The complexity of the food industry has compelled researchers to adopt complex, novel, and cross-disciplinary research tools. Neuroscience has provided the kind of innovative and precise methodology that is proving effective in examining the complex interactions of producers, customers, and patients. Neuroscience in the food industry encompasses several different areas of investigation and concerns diversified interested parties, offering novel methods of understanding how alimentation affects one health and everyday life. In addition, neuroscience enhances the development of medicine and marketing. It helps doctors and patients choose more effective methods of combatting diseases and select

proper nutrition. It also facilitates the growth of food producers and distributors by showing them how to make their products more competitive in the ever changing market.

Introduction

Consumers are becoming increasingly more informed about food systems and are interested not only in healthy, safe, and tasty food but also sustainable production, animal welfare, climate changes, and food waste. Consumers are also more focused on changing their lifestyle related to improved health knowledge and nutrition education (Timmer 2005). Maxwell and Slater (2004) have proposed criteria to evaluate food systems, including nutrition and health, rights and influence, security, sustainability, equality, and social inclusion. The authors also point out that the primary international institutions in the food value chain are not only the Food and Agriculture Organization and World Health Organization but also United Nations Industrial Development Organization, International Labour Organization, and World Trade Organization.

The emerging trends in the food system are features of the “new economy.” This term describes the outcome of the transition from

production- and manufacturing-based economy to a service-based or post-industrial economy at the end of the twentieth century. The traditional production factors such as cheap labor, land, and raw materials lose their importance in generating profits and competitiveness. The key is understanding of food consumer demand, knowledge of food industry and agriculture employees based on creativity, and flexibility of processes of production.

The Relations of New Economic Systems and the Food and Agricultural Industries

The new economy concept is primarily the result of sociocultural, economic, and technological changes. This paradigm is related to the economy as a social activity. From this point of view, one of the crucial issues in the new economy is justice that reverses the trend towards greater inequality and continuing economic disparities. It means that the “security” in this kind of economy could be based on relationships, community, and collaboration rather than wealth and accumulation of capital. Companies in the new economy have to be more “consumer-centric” (Hammer 2000). Ideas for being sustainable, environmentally friendly, and ecological are crucial. Finding new ways to use and re-use or recycle the resources are common trends.

Another essential element of the new economy is technological change. It relates to the introduction and development of emerging technologies and the increase of science-intensive economy. It is mainly seen in high technology sectors such as robotics, electronics, telecommunications, chemistry, biotechnologies, pharmaceuticals, and air and space technologies. Information and communications technologies (ICTs) play a unique role in the development of the new economy as they contribute to the transformation of social and economic structures due to the development of human relationships through various devices that primarily use the Internet. It is worth paying attention to the fact that in many cases these new relations are also of an economic nature, but they lack appropriate legal regulations that cannot keep pace with

changes in the economy. This phenomenon is explained by concepts such as the “cultural lag” (W.F. Ogburn) and “future shock” (A. Toffler).

This entry will present selected ideas of new economic systems that underline specific sectors that are also associated with changes in the food and agriculture industries. These are: (1) the sharing economy, (2) the circular economy, (3) the blue economy, (4) the creative economy, and (5) the digital economy. Many authors use these concepts interchangeably or as interconnected. For example, the sharing economy is sometimes described also under the notions such as the access economy, the labor-light economy, the freelance economy, the gig economy, the platform economy, the on-demand economy, the collaborative economy, the peer-to-peer economy, the reputation economy, or the trust economy. The circular and blue economies may be interpreted as further developments of ideas such as the green economy, the purple economy, the hydrogen economy, the biobased economy, and the decarbonized economy. The analyses of the creative economy are extended by notions of the attention economy, the experience economy, the post-scarcity economy, the conceptual economy, and the cognitive-cultural economy. Finally, the digital economy is sometimes described with related concepts such as the information economy, the knowledge economy, the learning economy, the industrial information economy, the new manufacturing economy, the network economy, and the virtual economy.

Sharing Economy

The food systems in many countries have become so industrialized that most of the food production processes are done by unknown people using unknown technologies in unknown places. Nevertheless, consumers buy and consume food, which means that they trust in food and its producers and processors. In recent years, the sharing economy has been on the rise, and it is predicted to generate a significant impact on the economy and society in general (Hamari et al. 2016). This concept refers to sharing of the use of assets that

have the untapped or unused capacity. Individuals participate in sharing activities by renting, lending, trading, bartering, or swapping goods and services (Heo 2016). The sharing economy includes networking opportunities for business that might not exist in a different system.

Meal sharing (such as communal dinner experience) is an example of the kinds of solutions, social interactions, and motivations for participating in new activities (Böcker and Meelen 2017). In countries all over the world, bake sales and in-home restaurants are becoming more common. Unfortunately, there is a considerable problem with regulation of this kind of trade, because in many countries selling homemade food is illegal and there are problems with no standards of hygiene.

Another category of motivation for the sharing economy is the environment. For many people, their involvement in the sharing economy is essential to reduce their use of scarce natural resources and increase efficiency in the use of goods (e.g., the zero-waste movement). The idea of sustainability and “to be green” are valid drivers among sharing economy users (Böcker and Meelen 2017; Hamari et al. 2016). In many countries, the initiatives for sharing include food banks, leftover food from individuals, or surplus food from supermarkets. Such activities are aimed at limiting the amount of food waste. Moreover, the sharing economy is characterized by relations between the providers and the users with economic incentives for cooperation. For example, kitchen owner can earn extra income from renting their space when it was previously not being used, while housing and supporting another business.

In this new economic system, entrepreneurs value the reclamation of the commons through the open sharing of knowledge, resources, and tools. The examples include the open source software movement and open source hardware projects utilized in, for example, shared labs for food processors, fab labs, and living labs related to agriculture projects, or urban farming spaces. Food companies are increasingly interested in ideas such as open innovation or triple and quadruple helix model of innovation, where the source of changes in products and services are

based on ideas originating from outside the enterprise.

It is important to underline that the notion of sharing economy that emerged at the early twenty-first century is sometimes confused with the features of earlier concepts such as the informal economy, the gift economy, the barter economy, the subsistence economy, and the idea of the social and solidarity economy (also known as the popular economy, the economy of the poor, the economy of local communities, the civic economy, the labor economy, and the cooperative economy). The concept of the social and solidarity economy emerged in Europe in the first half of the nineteenth century and still plays a significant role in the poverty reduction. The premise of this system is the activation of disadvantaged groups including farmers and people living in rural or peripheral areas through autonomous, collaborative, and democratic governance of entities such as social enterprises, cooperative banks, mutual insurance companies, fair trade organizations, including the food production certification systems, associations that are establishing local currencies, participatory budgeting models, self-help, and mutual aid groups.

Circular Economy

The notion of circular economy underlines collaborative models as essential to maximizing utilization of already used products and resources (Geissdoerfer et al. 2017). The necessity of using products in the circular flow is modeled after natural resources, for example, timber, food, and technical resources such as metals and minerals. These resources have to be transformed and used in the long term to implement the idea of “nothing is lost.”

Achieving the circular economy is especially related to reduction and sustainable use of natural resources, use of resources with less environmental pressure, and prevention of resource waste in processes of production and residue streams. The implementation of this model covers changes in technologies used in production, new methods of resource processing, and changing consumers’ habits and governance policy.

One challenge to a circular economy in the food system is closed loops of resources. For example, the traditional agriculture uses the well-known mechanism of returning nutrients to farms by turning agricultural waste into fertilizer. The benefits of it are regeneration of soil and reduction of reliance on artificial fertilizers. Another critical issue is recovering resources from by-products. It can be implemented, for example, recovering energy from alternative renewable feedstocks, which are the result of food production.

The optimization of crucial elements of food and agriculture production and manufacturing helps to save some soil, water, energy, and nutrients but cannot be done without looking at feed, cultivation, and breeding safety standards. Sometimes the residue stream is contaminated and it is not possible to use it in the food production. Or it requires too many other resources for treatment for secondary usage. Sometimes various kind of waste cannot be used in the production, for example, animal bones in food for people. Thus, the food wastage has to be used effectively in the food processing as well as under the law.

Another concept in the circular economy is the short supply chains, also known as “farm to fork.” The carbon footprint is lower, and it is positive for the local labor market. There are beneficial digital technologies that allow to measure, track, and locate food and other organic materials with more precision enabling better management and allocation of resources. It is also vital to understand and change consumers’ habits. Consumers increasingly are interested in buying organic food. They want to know the source of food, the methods of their production, and are interested in reducing waste. Food labeling – and better consumer understanding of labeling – is important to achieve these values.

The idea of the circular economy has a considerable influence on developing innovative food products and services in the food industry and agriculture. For example, urban farming gives the ability to produce food on underutilized urban roof spaces. This idea also has environment benefits by reducing building energy demands and allows the use of rainwater. Even

transnational corporations started to notice and support such trends. Another kind of innovation in this field is the production of fruits and vegetables in the shape right for crisps, chips, and other products, both for the sake of consumers and to decrease costs of transportation. This innovation reduces losses in the processes of peeling and cutting the products. One of the reasons for production of “lab-grown meat” is to find new sources of proteins coming from more efficient processes. It is especially important because the food produced in the food systems is also used to feed animals for meat production.

Blue Economy

The circular economy is closely related to the implementation of the idea of the blue economy. This notion refers to some options for economic development, in which economy responds to the needs of people. The blue economy stimulates entrepreneurship and new job opportunities (Pauli 2010). The primary focus of the blue economy is eliminating waste and pollution. It has to be based on scientific analyzes that identify the best solutions in business. Also, the social capital that is cooperation and trust between economic entities plays a significant role in the production of healthier and cheaper products (also known as the development of the “white economy”).

Elements that make-up the concept of the blue economy are: innovation, market, cash flow, and potentials. Innovation is the engine of growth in the blue economy. It is essential to identify the problems and find innovative solutions and opportunities. Significant is a market because sometimes consumers are conservative and slow adopt novel solutions and products. Cash flows can be generated without any public subsidies, but for example, by transforming the waste into new raw materials. The innovations can generate new potentials for new sources of cash flow, new jobs, and build social capital.

The concept of the blue economy is also known as the “ecology,” or an approach to business based on strict environmental and ethical principles that is also sustainable and

commercially profitable (Druon 2015). The concept of the blue economy can be seen as an alternative to the green economy. Green products are still categorized as luxury products, while green economy projects rely on special funds, subsidies, and tax cuts leading to thinking that implementation of this concept is expensive and not affordable for all countries. The blue economy provides ways, strategies, and alternatives which could overcome the current environmental problems. This idea is attractive for the food and agriculture industry.

Some shared concepts of the blue economy and circular economy are upcycling, recycling, remanufacturing, industrial ecology, and renewable energy. The fundamental idea of the blue economy is the cascading nutrients and energy in the ecosystems. An example of this is the idea of production of mushrooms grown on coffee-grounds as a by-product.

The idea of a blue economy is sometimes modeled on the concept of biomimicry (Benyus 1997). The main idea of it is to inspire from the genius of nature to innovate biotechnologies or processes that imitate nature. The biomimicry means adoption of solutions which are extracted from the evolution of nature. Products from such systems are less energy intensive, provide less adverse external effects to the environment, and are also probably healthier. In the context of the food production and manufacturing, this idea is represented by terms such as natural, bio, bio-agriculture, and eco-economy.

An example of technological biomimicry is juice bottle design created in essence of the pistil structure of a flower. An agricultural biomimicry example is growing food with using the prairies as a model system for producing stable natural ecosystems. Another example inspired by nature can be even the living filtration system as an alternative form of farm drainage. In contrast to modern farming that relies heavily on artificial fertilizers that get washed away and pollute water in rivers, this solution can trap nutrients in the soil. The blue economy assumes that it requires creativity from the society, including the employees of organizations.

Creative Economy

One of the main features of the new economy is creativity: thinking about new things or making an original combination of existing elements. The effect of creativity consists in breaking up a learned pattern of thinking and using its knowledge to generate new ideas. Most theorists have defined creativity as the development of ideas about products, practices, services, or procedures that are novel and potentially useful to an organization. Creativity depends on the context in which new products, ideas, and behaviors are offered (Klimczuk-Kochańska 2017).

There is a relationship between creativity, design, and innovation. For example, Baer (2012) treats innovation as an umbrella concept that includes creativity and its implementation. Florida (2002) shows that nowadays there is a transition from blue and white collars workers to no collar workers; it is a trend of development of a creative class represented by knowledge workers, intellectuals, designers, and artists. The developments in the creative industries such as design, mass media, and marketing are also related to ideas such as the silver economy or the longevity economy that drawn attention to new products and services for ageing and older consumers, including food, pharmaceuticals, dietary supplements, and innovative kitchen equipment for people with disabilities (Klimczuk 2015).

The idea of the creative economy is also found in the food sector. It is difficult to analyze the topic of creativity and innovation in the field of traditional industries with low technological potential, which is generally considered in the literature as characterized by low creativity and limited innovativeness. Changes in world market trends show that the development of the low-tech sector is in a state of confusion, that is, without a focus on innovation and encouraging employees to take creative action. Focusing on radical innovations may not be particularly important for the food business because of the conservative consumer behavior described as consumer inertia. Especially design-oriented concepts require not only the technical knowledge but also the creativity of the organization's employees. Without the

creativity, many food products and related services with different taste, color, or packaging would never have been created.

Digital Economy

Another significant aspect of the new economy is the digital economy. Digital economy refers to an economy that is based on digital computing technologies. Solow (1970) was implying the impacts of technological and scientific development in the present understanding of the effects of ICTs. This technical change leads to, for example, faster growth in manufacturing productivity. The digital changes are found in e-business infrastructure (hardware, software, networks, and human capital), e-business (business conducted over computer-mediated networks), and e-commerce (transfer of goods online) (Mesenbourg 2001). Nowadays, it seems that the change in the ICTs, lower prices for IT devices such as smartphones and tablet computers, and growing availability of Internet and Wi-Fi networks are vital aspects supporting the substantial growth of the sharing economy. For example, thanks to these opportunities to interact with other people, especially the Millennials who are already well-connected and networked and value the realness, honesty, and authenticity of things in life (Van den Bergh and Behrer 2016). This generation is considered the leading adopters of the solutions from the field of the sharing economy.

The digital economy can lead to sale prices close to zero or free. It may not only create many businesses, but now most of the companies are threatened by the digitization of the economy. The most popular concepts are now, for example, the Internet of Things (IoT), blockchain, big data, and e-commerce.

In the food and agriculture industry, the digital economy integrates the agile culture and processes through a whole supply and value chains. It is crucial because of many reasons but mainly for healthy and safe food. The digital technologies in food production and manufacture can be used in solving problems, such as the traceability of food and the use of satellite tracking of lorries

delivering food to distribution centers. However, the transportation also includes the critical issue of collecting data from the course of transport and, for example, changes in temperature in a cold store truck. Significant are bases of “data trust” which for the food sector help to underpin data sharing, trust, and inter-operability within complex supply chains.

Although there are interesting potentials for growth, many agri-food and agricultural enterprises still have not bridged the digital divide. Moreover, the IoT solutions are increasingly related to services for consumers. An excellent example is a use of smart refrigerators and cooking devices to improve health outcomes and reduce waste.

Conclusion

This entry examined various economic systems related to the broader idea of the new economy in food and agriculture, namely, the sharing economy, the circular economy, the blue economy, the creative economy, and the digital economy. These systems support and use different forms of capitals and technology changes. However, none of these systems can meet all the needs of the food industry and agriculture. These systems can, however, be mixed and combined by using features of a new economy to improve the competitiveness of food systems in light of current global trends.

Nietzsche and Food

Robert T. Valgenti
Department of Philosophy, Lebanon Valley
College, Annville, PA, USA

Introduction

Friedrich Wilhelm Nietzsche (1844–1900) was a German philosopher who is quoted as often as he is misunderstood. He is well known for his ideas of the “superman” (*Übermensch*), the “will to power,” and the “eternal return of the same,” along with his many quotable passages, chief among them is the proclamation that “God is dead.” It would be incorrect, however, to reduce his work to these ideas or even to take them as emblematic of his philosophy. This is no place to engage in a debate over Nietzsche’s philosophical contributions and importance, but a few key (but by no means comprehensive) themes in Nietzsche’s thought will help to guide the reader through Nietzsche’s language of alimentation and digestion.

The theme of (1) “health” expresses Nietzsche’s positive valuation of practices and attitudes that affirm life and the power of individuals (“free spirits”) and cultures to grow and transform. Unhealthy individuals or cultures are weak, passive, and “decadent” in Nietzsche’s vocabulary. The process of decadence and weakening over the course of Western history is what Nietzsche calls (2) “nihilism,” the realization that there are no more absolute values or irrefutable truths. The utter radicality of Nietzsche’s thinking replaces truths or facts with (3) “interpretation” – Nietzsche’s desire to perform a “transvaluation of all values” is not simply a desire to replace the Christian values of his day with different ones, but rather the full commitment to life as a process of becoming, to live as if no values were absolute and to understand value as the result of a creative and interpretative process. To be a “free spirit” and live with health, strength, and vital force denotes the ability to give oneself over to self-transformation – a process Nietzsche equates with healthy digestion.

Food and Diet in Nietzsche’s Life

Nietzsche’s own struggles with illness throughout his life shape his writing and philosophy. As per the common medical practice of the time, which often identified an illness’ cause and treatment in the stomach (Weineck 2006, p. 37), he attributes his various health problems to diet and in response often indulges his family’s propensity for homeopathic cures. Even though the famous physician Professor Oppolzer of Leipzig diagnoses his illness as cerebral and not gastric, Nietzsche commonly rejected the advice of doctors who suggested treatments that limited his intellectual activity; instead, he favored dietary remedies and treatments for his stomach: his long-time doctor friend Professor Immermann in 1875 prescribed silver nitrate and, upon its failure, high doses of quinine (which a friend remarked constituted “experiments on [his] poor stomach”) (Young 2010, p. 207); soon after, upon his arrival at a clinic in Steinbad, he placed himself under the care of Dr. Joseph Wiel, a cookbook author and doctor of questionable skill, who prescribed daily cold water enemas, four small meals per day comprised mostly of meat, and food cooked only in enameled pots – “no water, no soup, no vegetables, no bread” as Nietzsche remarks in a letter to Marie Baumgartner (Young 2010, p. 208).

While there is disagreement as to the proper diagnosis of Nietzsche’s various ailments, his stomach problems were most likely caused by irritable bowel syndrome, a condition that persisted for his entire life (Young 2010, p. 209). Nietzsche’s own obsessiveness over diet and gastrointestinal health explain in some measure why the stomach was so central to his philosophical notions of an individual’s or culture’s health. Moreover, it is important to note that while in his early thinking moral health leads to physical and psychological health, this causality is reversed in his later thinking, such that moral and psychological health are taken as the good effects of physiological well-being (Young 2010) that has its root in the processes of alimentation and digestion.

Here Is the Man and His Diet

Perhaps the clearest and most direct account of Nietzsche's own dietary habits and beliefs can be found in his autobiographical work *Ecce Homo*. This text arrives at the end of Nietzsche's intellectual production and provides a comprehensive dietary lens through which to view Nietzsche's mature philosophy. The stomach is the origin and cause of physical and spiritual (read: intellectual or cultural) well-being, even though they are never reduced to the body's health. This hierarchy marks a reversal of the traditional dominance of the spiritual (and the visual) over the bodily (and the gustatory). Unhealthiness is marked by decadence and decay, an inability to digest properly (dyspepsia), or an inability to convert what is digested into an intellectual or cultural transformation. Nietzsche claims he is not a decadent because he knows what to eat when he is ill; unlike the rest of society, he is able to digest and forget (Nietzsche et al. 2005, p. 76) and views himself as a living example of the positive, life-affirming qualities that distinguish the strong and vital spirit from one that is passive, weak, and unable to give itself over to transformation.

Nietzsche's dietary prescriptions for overcoming the weight of these traditions and for discovering a life-affirming power are, as his biography suggests, equal parts real and metaphorical (or, as is perhaps better suited to his philosophy, one that problematizes the distinction between the two). He cautions that he is too easily affected by wine and spirits (in vino veritas makes little sense once the idea of truth is rejected) and prefers drinking water out of running fountains (Nietzsche et al. 2005, pp. 86–87). He opposes vegetarianism; does not recommend long, protracted meals; avoids snacking between meals; shuns coffee; and only drinks tea in the morning. He refers to these prescriptions as his "morality," which includes the suggestion that one must "be aware of the size of your stomach" and choose hearty meals rather than ones that are too small because digestion involves the entire stomach (Nietzsche et al. 2005, p. 87). Of all diets (and cultures), he is most critical of the Germans, for "the German diet bears the weight of guilt (what doesn't it have on

its conscience!). . . German spirit is indigestion, it is never through with anything" (Nietzsche et al. 2005, p. 86).

Nietzsche views his own reading and writing through the lens of gastric health. One needs a "joyful belly" to read Nietzsche and to digest his "life-transforming" books (Nietzsche et al. 2005, p. 90). Those who remain silent and do not write transformative books like his are dyspeptic – lacking discernment in judgment and taste (the democratic spirit) – they swallow everything but do not properly digest it (Nietzsche et al. 2005, p. 80). This unwillingness and inability to change – the clinging on to worn out ideas of morality and culture – are the telltale signs of decadence, of the life-destroying power from which society must be saved. For Nietzsche it is a question of *nutrition*, for "the 'salvation of humanity' is much more dependent on this question than on any theological oddity" (Nietzsche et al. 2005, p. 85). If nihilism is the long, slow, decadent decline of Western, Judeo-Christian values whereby all ultimate values are shown to be baseless, any recovery from or overcoming of that condition – what Nietzsche refers to as an active or accomplished nihilism – requires first and foremost a healthy body that can incorporate the foreign and partake in a continual process of self-transformation. Nietzsche suggests that nutrition, the practices that support life-affirming forces and engage the process of becoming and transformation, requires an unapologetic embracing of one's own identity rather than a conception of self that is shaped by the herd mentality of prevailing cultural values.

A Critique of Modern Dyspepsia

For Nietzsche, the digestive process is analogous to the intellectual process of understanding and interpretation, with dyspepsia indicative of the individual or culture that consumes knowledge but does not actively metabolize it in a transformative way. Knowledge is not simply some fact or idea "out there" in the world, but something brought to consciousness and understood within the context of one's own life – to know is to interpret

experience in a manner fitting to one's own perspective. In his second *Untimely Meditation*, Nietzsche first utilizes digestive language to describe modern culture's unhealthy relationship with its own past as "a huge quantity of indigestible stones" of knowledge "consumed for the greater part without hunger" and no longer received "as an agent for transforming the outside world." Such a culture will "perish of indigestion" (Nietzsche and Hollingdale 1997, pp. 78–79). In this early work, Nietzsche views the moral and spiritual health of an individual or society as the cause (not yet the effect) of its "bodily" health and vital energy – if one is morally and spiritually healthy, one can approach knowledge of the past as a cure and an aid to well-being; if taken in the wrong manner, however, knowledge becomes a culture's "historical illness."

In the years 1876–1879, Nietzsche's struggles with his own illnesses are accompanied by an increase in gastro-rhetoric. In *Human, All Too Human*, Nietzsche casts his own work in the light of a healthy stomach: "Writing ought always to advertise a victory—an overcoming of *oneself* which has to be communicated for the benefit of others; but there are dyspeptic authors who write only when they cannot digest something" (Nietzsche and Hollingdale 1996, p. 248). In terms of lived experience, he comments that "everyone nowadays lives through too much and thinks through too little: they are ravenously hungry but at the same time suffer from colic (dyspepsia), so they get thinner and thinner however much they eat.—He who says nowadays 'I have experienced nothing'—is an idiot" (Nietzsche and Hollingdale 1996, p. 360). The key to experiencing life is not a distanced, objective, or even scientific reflection on it; rather, the experiences of life nourish thought, while, in a reciprocal manner, thinking enriches and transforms the experience of life: "For as long as one is experiencing something one must give oneself up to the experience and close one's eyes: that is to say, not to be an observer of it while still *in the midst* of it. For that would disturb the absorption of the experience: instead of a piece of wisdom one would acquire from it indigestion" (Nietzsche and Hollingdale 1996, pp. 385–386). "Wisdom"

is the product of healthy digestion and transformation into life rather than the mere consumption and preservation of life's experiences.

A telling illustration of the connection between good digestion and vital, transformative energy can be found in Nietzsche's critique of modernity and, most notably, his critiques of selfless, Christian moral values and the "herd" mentality of modern democracy and socialism. In a decadent society, "modern man understands how to digest many things, indeed almost everything," but in a manner that does not transform him inwardly, but only reduces the external world to consumable material – he is "*homo pamphagus*" (Nietzsche et al. 1997, p. 104). Nietzsche is also skeptical of pessimists and misanthropes unwilling to embrace the transformative potential of human creativity. Any deep dissatisfaction with existence is usually caused by "some great dietary mistake made by people over a long time" (Nietzsche et al. 2001, p. 124); and the misanthrope "speaks of being sick of people only when one can no longer digest them and yet still has one's stomach full of them" (Nietzsche et al. 2001, p. 135). These images of the undisciplined eater who lacks a discerning sense of judgment or taste is perhaps the most common of all Nietzsche's gastric tropes.

Nietzsche's allegory *Thus Spoke Zarathustra* continues this critique of weak, modern individuals. On the one hand, they represent the herd and the rabble, those without discerning judgment who "are always sick, they vomit their gall and call it the newspaper. They devour one another and are not even able to digest themselves" (Nietzsche 2006, p. 35). In this inability to judge, however, one simply becomes omnivorous and devours everything: the "all-complacent . . . knows how to taste everything—that is not the best taste! I honor the obstinate, choosy tongues and stomachs, which have learned to say 'I' and 'Yes' and 'No.' But chewing and digesting everything—that is truly the swine's style! To always say hee-yaw—only the ass learned that, and whoever is of its spirit!—" (Nietzsche 2006, p. 155). If one wishes to be a free spirit able to undergo a transformation, one must protect the stomach by eating what is best and not what is most available: "their spirit is a ruined stomach: *it* recommends

death! Because truly, my brothers, the spirit *is* a stomach!” (Nietzsche 2006, p. 165). Such a spirit is ready for transformation and the break with tradition, which requires taste, judgment, and critique. Zarathustra criticizes the beggar whose stomach “resists all such raging and hating and foaming over. Your stomach wants gentler things: you are no butcher. Rather, you seem to me a vegetarian and a root man” (Nietzsche 2006, p. 219). This last image not only seems to confirm Nietzsche’s suspicion about vegetarians but also rejects those who are slow to change and cling to tradition.

Nietzsche believes that European culture in the nineteenth century, and most notably German culture, promotes traditional moral ideas that are hostile to life-affirming change and transformation. These false “free spirits” of Europe have “teeth and stomachs for the indigestible” (Nietzsche et al. 2002, pp. 41–42) and like any herd has a “crude appetite” for whatever is shoved down its throat. Their narrow-mindedness is equated to a slow speed of digestion, and Germans in particular digest in a slow, hesitating manner (Nietzsche et al. 2002, pp. 132, 135). In *On the Genealogy of Morality*, Nietzsche claims the healthy individual can forget and digest, while those who cannot forget or shut off their digestion are “like a dyspeptic—he can get rid of nothing, cannot metabolize it” (Nietzsche et al. 1998, p. 35). Such individuals also misinterpret the origin of “bad conscience” or guilt – understanding its true origin (in material culture, rather than the soul) requires “digestions” and “meditation.” Nietzsche’s entire critique of modern morality, and his belief in the “untimely” nature of his critiques, might be summed up in the following image: “We have probably all sat at tables where we did not belong; and the most spiritual among us (who are the most difficult to feed), are familiar with that dangerous dyspepsia that comes from a sudden insight into and disappointment over our food and dining companions,—the *after-dinner nausea*” (Nietzsche et al. 2002, p. 170). Even though his society is in decline, Nietzsche’s understanding of nihilism (the baselessness of all values) allows him to redeem humanity

through its continual transformation – a process that requires an ability to digest what is other and interpret it in light of one’s own transformative perspective or “will to power.”

The Free Spirit of Digestion

If the two flaws of modernity find their alimentary expression in the inability to digest, and in a ravenous but undiscerning appetite for various forms of knowledge, Nietzsche’s remedies are expressed through a vital ability to digest, metabolize, and incorporate what is foreign and through a discerning dietary judgment known as “taste.” This is not merely a matter of nutrition or aesthetics, but promotes a direct causality between the gastrointestinal health of the body and the spiritual health of an individual or society. Near the outset of *The Gay Science*, Nietzsche asks “Do we know the moral effects of foods? Is there a philosophy of nutrition?” to guide the growth of individual and shared life (Nietzsche et al. 2001, p. 34). Nietzsche not only suggests a reversal of traditional mind-over-matter causality but implicitly rejects any reduction to an absolute causal relation one way or the other. Nietzsche is, above all, simply concerned with the way that power is expressed in human life – the stomach is but one way of illustrating that expression.

For this reason, Nietzsche is able to admire the powerful origins of individuals and institutions he often condemns. In their early, non-decadent forms they illustrate a will to power and vitality of life through the processes of becoming and transformation, such as one finds in “the astonishing crudeness and self-satisfiedness of the church’s intellect during the time it was in process of formation, which permitted it to accept *any food* and to digest opposites like pebbles” (Nietzsche et al. 1997, p. 42). The strong stomach is an organ that allows one to endure pain and transform life’s insipid repast (Nietzsche et al. 1997, p. 166). Invoking an image that also appears in *On The Genealogy of Morality*, Nietzsche’s Zarathustra reflects: “My stomach—it must be the stomach of an eagle? Because what it loves best is flesh of lamb. Certain at least, it is the stomach of a bird. Nourished by innocent things and

by a little, ready and impatient to fly, to fly away—that is just my way” (Nietzsche 2006, p. 153). This digestive freedom constitutes a very particular sort of power, as it is open to otherness and yet (somewhat paradoxically) unabashedly egoistic. Digestion in this sense constitutes a form of interpretation: one does not merely passively accept and become what is taken in; nor does one actively destroy and assimilate the other completely into oneself. The model here is reciprocal, with the healthy eater allowing herself to be transformed only to the degree that the process is also transforming and shaped by the eater; and through that transformation, the other and the self are metabolized, literally, thrown-beyond themselves into something new. Artistic or cultural creation (great works, new paradigms, moral values, etc.) is not ex nihilo, but arrives through process of incorporation and transformation that is an interpretation or, in Nietzsche’s more popular terminology, an expression of “will to power.”

The ability to create in this way – an act that ultimately constitutes a form of interpretation guided by a hierarchical (re)ordering of values – relies on a certain degree of taste, an ability to judge, and carefully select what one ingests and what one allows to participate in the transformative metabolism of the self. This ability to discern and judge arises from a certain mode of life, the nourishment and diet of the “tastemakers” (Nietzsche et al. 2001, p. 56). Nietzsche claims that “you must eat, not only with your mouth, but also with your head, so that you shall not perish by the mouth’s love of sweetmeats” (Nietzsche and Hollingdale 1996, p. 278). More than a heightened cultural or artistic sensitivity, there is a level of rational control over what and how much one takes in: rather than coming to the table hungry and at the mercy of one’s appetites, one deals with people and one’s society as if one were building trust in a kitchen whose cook is unfamiliar (Nietzsche et al. 2001, p. 229). In an aphorism (displaying Nietzsche’s not uncommon misogyny) entitled “Stupidity in the Kitchen,” Nietzsche claims that women have no knowledge of philosophy and the effects of food. The stomach, like the soul, should be guided by our reason and discerning will rather than by the loss of its control

(Nietzsche et al. 2002, pp. 125–126). These thoughts do not promote rationalism, a tradition in philosophy that Nietzsche clearly opposes; yet, Nietzsche is not simply an irrationalist who wishes to relinquish the will to passivity and emotion. One could argue that for Nietzsche, a healthy will is guided by active and egoistic reasons and motivations – an unapologetic confidence is one’s own tastes and ways of doing things.

This thinker or “free spirit” lives on poor fare, like a dancer: “There is no formula for how much a spirit needs for its nourishment; but if it has a taste for independence, for quick coming and going, for wandering, perhaps for adventures of which only the swiftest are capable, it would rather live free with little food than unfree and stuffed” (Nietzsche et al. 2001, p. 246). Nietzsche is not advocating, however, a life of the ascetic (whose complete restrictiveness undermines good digestion, as he points out in Treatise III of *On the Genealogy of Morality*). One has to understand how much and what sorts of food to ingest, which virtues and ideas to accept, and which ones to reject: “Each of these choices—of nutrition, of location and climate, and of recuperation—is governed by an instinct for self-preservation that is most clearly expressed as an instinct for *self-defence*. . . . The usual word for this instinct of self-defence is *taste*” (Nietzsche et al. 2005, p. 95). Nietzsche does not propose a simple reduction to Darwinian self-preservation; rather, the “free spirit” validates his own perspective or interpretation through its defense, through a desire to be uncompromising and often untimely.

Is the Stomach the Heart of Nietzsche’s Philosophy?

For Nietzsche, a healthy and vital digestive power involves a discerning openness to new ideas and an ability to incorporate those ideas in a process of becoming: “all of which are necessary in proportion to the degree of its appropriating force, its ‘digestive force,’ to speak metaphorically—and *really*, ‘spirit’ resembles a stomach more than anything” (my italics, Nietzsche et al. 2002, p. 122). Nietzsche certainly problematizes the

line between the real and the metaphoric, as neither the spirit nor the body are simply “facts” or givens to be reckoned with. They are themselves modes or ways of interpreting the world that cannot be reduced to a purely physiological explanation of cultural and individual health: “A strong and well-constituted individual digests his experiences. . . . If he ‘cannot cope’ with an experience, this kind of indigestion is just as physiological as that other one—and in many cases in fact only one of the consequences of that other.—With such a conception one can, speaking among ourselves, still be the strictest opponent of materialism” (Nietzsche et al. 1998, p. 93). This claim is, however, difficult to reconcile with the seemingly more materialistic and reductionist position Nietzsche takes in *Twilight of the Idols*: “It is crucial for the fate of individuals as well as people that culture begin in the *right* place—not in the ‘soul’ (which was the disastrous superstition of priests and half-priests): the right place is the body, gestures, diet, physiology, *everything else* follows from this. . . .” (Nietzsche et al. 2005, p. 221). Such contradictions are not uncommon in Nietzsche’s philosophy and in many ways point to the active and interpretative criteria to which he held even his own thinking.

Ultimately, should the metaphor of digestion be taken only as that – yet another rhetorical device employed by Nietzsche the writer to help illustrate, in a mode other than traditional philosophical argument, how humans relate to the cultural ideas that shape their social environment? Or should digestion be understood in a more literal and existential way – namely, as the physiological basis and source of human cultural production and self-understanding? The status of these digestive tropes is the subject of some academic discussion and mirrors a more general debate in Nietzsche scholarship over the degree to which Nietzsche is a materialist. In *Nietzsche: The Body and Culture*, Blondel argues that Nietzsche’s gastric metaphors are themselves metaphors for interpretation, with interpretation itself serving as an ultimate yet circular principle through which new cultural ideas arise and old ones are either reincorporated or overcome in the “body” politic but not, however, reduced to the physical human body (Blondel

1991, p. 219). In the end, the strength of a culture is associated with its ability to change, grow, and be discerning about what it chooses to “incorporate.” Nietzsche’s metaphors of digestion are thus “a scheme with which to interpret culture as interpretation” (Blondel 1991, p. 229). Medeiros argues that, at least in the practice of reading in *The Gay Science*, devouring and interpretation are interchangeable. Medeiros criticizes Blondel’s strictly metaphoric interpretation and argues that politics, morality, and art should be viewed as extensions of physiological acts (Medeiros 1993, pp. 96–97). Weineck places Nietzsche’s digestive tropes in the interpretative middle between consciousness and physiology, suggesting that Nietzsche “re-literalizes” digestion as spirit embodied, replacing Hegel’s *Aufhebung* with a form of overcoming and becoming that by design resists its own completion and absolutization (Weineck 2006, pp. 37–39).

How to Become What You Eat

In the figure of digestion, Nietzsche undermines the mind-body distinction so that the process of interpretation is reduced neither to pure cognition nor to pure physiology, illustrating how to digest and metabolize the very distinction between body and mind and nature and culture. Digestion points to a hermeneutic circle of interpretation that, without any absolute foundation, is always on its way to the next interpretation, always in a process of becoming, always metabolizing. Nietzsche’s autobiography *Ecce Homo* carries the subtitle “How to Become What You Are.” In light of the maxims put forward by two other thinkers of the nineteenth century (Feuerbach’s “you are what you eat” and Brillat-Savarin’s “Tell me what you eat, and I will tell you what you are”), one could perhaps summarize Nietzsche’s meditations on digestion, and perhaps the whole of his philosophy, with the revision: “how to become what you eat.” Unlike his contemporaries, Nietzsche does not offer us a description of human existence and understanding nor even a prescription. Life – physical or cultural – always carries with it the risk that accompanies any ingestion, whether of

food or ideas. To consume and digest, and thus to think and create, is (somewhat paradoxically) to assert oneself in the act of transforming into something other, to be open to otherness when becoming who one is.

Introduction

Obesity presents a major set of issues relating to health and society. These issues arise at local, national, and international levels, effecting individuals, families, communities, health infrastructure, and on some accounts, even the global climate (Egger and Swinburn 2010). Given the individual and collective costs of obesity, many (Egger and Swinburn 2010) are calling for an organized response to the problem. While there are a number of different ways of responding to

obesity, one particularly important and contentious set of responses centers on consumer choice, particularly their food choices. That is, given consumption's causal role in obesity, consumer food choices present a key intervention point to reduce obesity levels. This entry looks at discussions around, in support of and in opposition to, consumer choice as a morally justifiable and practically worthwhile way of reducing obesity.

This entry begins with a background summary of ways that obesity has been characterized, as being overweight, body mass index (BMI), waist-to-hip ratio (WHR) or waist circumference (WC), total body fat, and visceral adipose tissue (VAT). It then looks at individual health concerns about obesity and the changing rates and spreads of obesity in the past few decades. The entry covers the relative importance assigned to obesity, as a problem of individual health, public health, wasted food, and wasted arable land. In order to understand the rise of and ways of responding to obesity, a set of causes are explored, including the "simple model" of too much energy in, not enough energy out; individual genetics; lifestyle; food amounts; food types; food desirability; and food availability and access. Consumer choice is then identified as one way of responding to a number of obesity's causal factors. Consumer choice itself is then characterized in a number of ways covering the range of options to consumers and the consumer's capacity to make decisions regarding their food consumption. The chapter then looks at proposed government interventions

in consumer choice to decrease obesity rates and finishes with a summary of reasons for and against government intervention in consumer choice.

Background

Obesity is a major issue. For example, in the United States, three in five members of the adult population are estimated to be currently overweight, and one in five is estimated to be obese (Pollan 2006, p. 102). While the United States is often held as a paradigm example of the obesity epidemic (Kessler 2009, pp. 3–6), this pattern is common across most western countries and is now being replicated in emerging economies like India and China and in the developing world (Kessler 2009, pp. 111–114; Schlosser 2003, pp. 242–243). The rate and spread of obesity has shifted. Since the 1970s, rates of obesity have risen dramatically (Egger and Swinburn 2010, pp. 10–13; Roberts 2008, pp. 89–90). The distribution of obesity within the population has shifted – where obesity once manifested in adult years, child obesity rates have rose in the period 1980–2000 (Roberts 2008, p. 89) but may have now leveled off (Ogden et al. 2012). Similarly, obesity was once fairly restricted to economically well-off, but is becoming more prevalent in the poor of the developed world (Roberts 2008, p. 96). Finally, those in the developing world are now replicating the obesity rates found in the developed world (Egger and Swinburn 2010, pp. 13–14; Schlosser 2003, pp. 225–252).

These rates of obesity are worrying, not simply because they are increasing but because of the costs to individuals and the increased burden of non-communicable disease to national health-care infrastructure – The US Centers for Disease Control (CDC) put the costs of obesity and its related diseases at US \$75 billion and linked it to 112,000 premature deaths (Roberts 2008, p. 83). Some draw links between obesity in the developed world and starvation in the developing world (Patel 2007), while others draw links between the rise of obesity and climate change (Egger and Swinburn 2010, pp. 52–64). In short, many

see obesity as one of the major health and environmental concerns of this century.

Part of the problem with obesity is that it is a “complex problem,” with many associated causes (Roberts 2008, p. 84) and many possible ways of treating the problem. As such, obesity raises a set of correlated empirical, conceptual, and ethical questions – What is it? What causes it? How can societies respond? How should societies respond? Should societies respond at all? Given that obesity is caused in part by certain patterns of food consumption are typically implicated in the recent rise of obesity, consumer choice is seen as one key way of intervening to treat the problem (Egger and Swinburn 2010, pp. 80–83). “[O]ur bodies are far more efficient at gaining weight than at losing it. Health officials have concluded that prevention, not treatment, offers the best hope of halting the worldwide obesity epidemic” (Schlosser 2003, p. 243). However, even if this is practically feasible, as this entry will show, such interventions – especially if centrally organized through government sponsored programs – in consumer choice are controversial and face opposition.

What Is Obesity?

How has obesity been characterized? Firstly, and most obviously, obesity means a person is overweight: the obese person has more weight than is normally considered healthy. However, as this simple description shows, obesity is more than simply being overweight. Obesity refers to some deviation from a normal weight range that correlates with some associated health concerns. A sensible definition of obesity must include something more than “overweight”; it must have some measure of normal weight range and the associated deviation and must have some explanatory association with health.

One of the most commonly used measures is body mass index (BMI). This was first described by Adolphe Quetelet in the late nineteenth century (Egger and Swinburn 2010, p. 20). However, the BMI is a coarse indicator and may not necessarily correlate with health concerns – rugby players, for

example, can display a BMI in the obese range, while being exemplars of good diet and peak physical health (Egger and Swinburn 2010, pp. 20–21). More recent measures include the waist-to-hip ratio (WHR) and waist circumference (WC). In WHR, men and women are said to be obese when their waist is larger than their hips by a ratio of greater than 1 or 0.9, respectively, or display a WC of 102 and 94 cm, respectively (Egger and Swinburn 2010, pp. 21–22). Though perhaps a more reliable indicator of health concerns like the BMI, WHR, and WC are still a coarse correlative measure. However, being overweight is itself not necessarily the major concern. Instead, people should be focusing on the actual physiological risks that typically come with obesity, such as the visceral adipose tissue (VAT), in which internal fat around organs such as the kidneys and liver stomach has shown a strong correlation with insulin resistance and Type 2 diabetes (Egger and Swinburn 2010, p. 22).

The multiple definitions of obesity also point to the complexity of *dealing* with obesity; given the lack of consensus on definitions, consensus in responses would be surprising. For the purposes here, the general description of obesity, “some deviation from a normal weight range that correlates with some associated health concerns,” will be used to investigate responses to obesity.

Why Is Obesity Important?

Despite the multiple descriptions of what obesity is, there does seem to be a loose consensus that obesity is a major problem. Why are people concerned about these changing rates and patterns of obesity? Obesity is typically understood to correlate with health concerns. Obesity is may be an indicator, or a cause, of health concerns such as diabetes, heart disease, and cancer (Egger and Swinburn 2010, pp. 23). It is seen as important for the direct impacts that it has on individual health. In addition to the personal cost, obesity is a major public health issue. For instance, the annual costs to the American health care and economy in the mid-2000s by the CDC were said to be US \$61 billion and US \$56 billion on

direct medical cost and indirect costs including wages, respectively (Roberts 2008, p. 91). Given its increased incidence in childhood and its emergence in the developing world, the burden of obesity is expected to continue increasing.

A further concern is the waste of food and land. If obesity is a result of overeating, then such food is a waste and one that is especially problematic given the amount of people currently suffering from under-eating (Patel 2007, pp. 1–6). Similarly, given concerns about global climate change (Egger and Swinburn 2010, pp. 54–59) and reduced access to arable land, some hold that obesity is indicative of an unfair use of resources and arable land (Roberts 2008, pp. 144–174).

What Are the Causes of Obesity?

The simplest explanation for obesity is that people are taking too much energy in and not putting out enough energy, that is, eating too much and not exercising enough. This produces an oversupply of calories, which are then converted to fat, producing weight gain. When this imbalance is persistent through time, a person becomes obese (Egger and Swinburn 2010, pp. 10–18; Kessler 2009, pp. 7–8). However, such a description is simplistic. It does not identify causal elements nor explain why obesity spreads and rates have shifted so dramatically in recent decades (Egger and Swinburn 2010, pp. 19–27; Roberts 2008, pp. 88–91). Individual genetics are sometimes assigned a particularly important causal role; however, as with the energy imbalance explanation, assigning causal responsibility to genetics alone does not explain the shift in rates (Egger and Swinburn 2010, pp. 16–17).

One key element is changing lifestyle. Many now live lives that are much more sedentary than in any other time in human history. Many jobs are now minimally demanding physically, travel is typically by car or other transport, and when home people are more inclined to sit than be physically active (Pollan 2006, p. 110; Roberts 2008, p. 94). However, given the variation of lifestyles around the world, lifestyle alone is not likely to be the main causal factor.

In line with the simple idea that there is too much energy going in, i.e., overconsumption, increased consumption itself is posed as a major cause. Eric Schlosser writes “[w]hat has changed is the nation’s way of eating and living. In simple terms: when people eat more and move less, they get fat” (2003, p. 240), a point mirrored by Paul Roberts (2008, pp. 83–84). As one example of increased consumption, Roberts has stated that the serving sizes in recipe books have increased across the past decades (Roberts 2008, pp. 100–101).

Further to this, the actual content of what people are eating has changed substantially in recent decades (Pollan 2006, pp. 109–119; Roberts 2008, pp. 29–56). Schlosser writes that “[w]hat we eat has changed more in the last forty years than in the previous forty thousand” (Schlosser 2003, p. 7). For instance, while beef consumption in the United States was at 90 lb. per person in 1976, by the mid-2000s it was 68 lb. per person (Schlosser 2003, p. 142), to be replaced by chicken, largely due to the development of the chicken “nugget” (Pollan 2006, p. 114). Annual patterns of individual potato consumption have shifted heavily toward chips/fries, from 81 lb. of fresh potato and 4 lb. of french fries in 1960 to 49 lb. of fresh and in excess of 30 lb. of french fries (Schlosser 2003, p. 115). Similarly, restaurant/takeaway food represents 50% of food spending (Schlosser 2003, p. 4). Importantly for obesity, these food types are highly processed, leading to substantial increase in consumption of refined sugars, particularly high-fructose corn syrup (HFCS) (Pollan 2006, pp. 103–14; Roberts 2008, p. 92) and saturated fats (Egger and Swinburn 2010, p. 35; Roberts 2008, p. 97), which have been associated with raised insulin levels, decreased insulin sensitivity, and VAT (Egger and Swinburn 2010).

Recent work in the area of obesity suggests that rise in sugars, fats, and salt in processed foods contributes to increased consumption (Kessler 2009, pp. 12–17). Prior to the modern era, sugars, fats, and salt were in limited supply so humans evolved a strong flavor preference for these (Egger and Swinburn 2010, p. 35; Roberts 2008, pp. 84–89). Former commissioner of the US Food

and Drug Administration (FDA) David Kessler has recently argued that humans are hardwired into finding foods with a mixture of sugar, salt, and fats highly desirable (2009, pp. 3–64). As such, increasing the content of sugars, fats, and salt in processed food increases the desirability of such foods. Similarly, in recent times, advertising and placement of foods, particularly processed foods high in sugars, fats, and salt, have increased in sophistication and penetration (Schlosser 2003, pp. 43–55), leading to increased desirability for those advertised foods (Kessler 2009, pp. 50–54).

A further element is that the environmental conditions around consumption have changed. Availability and access to these processed foods has increased. Food distribution points such as schools, offices, and supermarkets make processed foods highly available (Schlosser 2003, pp. 51–57). Secondly, processed foods are often cheaper than fresh/unprocessed foods (Harrison et al. 2010; Pollan 2006, pp. 95–97). Further, the time taken between desiring to eat the food and consumption of the food is short (Kessler 2009, p. 95). Finally, the “cognitive environment” is similarly colonized by such food types: children are heavily targeted by fast-food company marketing (Schlosser 2003, pp. 42–47). Product placement in cultural and sporting events is common (Kessler 2009, p. 199), and Kessler explains that, given the sugar, fat, and salt content of such foods, mere mention is enough to trigger a desire to consume it (Kessler 2009, pp. 3–64).

What Is Consumer Choice?

Given that obesity is potentially harmful to individuals and can place great burdens on public health systems, many propose that there is a *prima facie* case for governmental intervention in food consumption. For instance, Egger and Swinburn state that “[i]nitiatives that identify the *population*, not the individual, as the unit of intervention are . . . likely to have the most impact on obesity and chronic disease” (Egger and Swinburn 2010, p. 39). One such point of intervention is at the product/consumer interface, for instance, reducing the size of serving plates and

packages, what Richard Thaler and Cass Sunstein call “choice architecture” (Thaler and Sunstein 2009, p. 44).

There are a number of ways to conceptualize consumer choice, and these different conceptions bear upon both the sorts of government interventions used to reduce obesity and how permissible they are. Beginning at the consumption element, consumer choice can be thought of as options – the range of food types available to consumers or, equally, the range of supplier types distributing food to consumers. However, consumer choice can also be considered within more common elements of philosophy, particularly the capacity to make decisions, knowing what those decisions mean, and reflectively endorsing those decisions.

Choice as Options

Often, consumer choice is equated with a range of options that the consumer can select between. For instance, consumer choice can be considered as the access that a consumer has between brand types in stores. It may also be considered as the range on a menu that they select from. Similarly, consumer choice can be considered as the range of different food types that a consumer has access to. A contrast can be made here between consumer choice as selecting between soda brands, between soda sizes, and between soda and juice. Importantly, some argue (Patel 2007, pp. 12–14) that given the monopolization of food suppliers and distributors, the actual difference between these options is limited. For instance, in the United States, the majority of beef that people eat (80%) comes from four main suppliers (Pollan 2006, p. 63; Roberts 2008, p. 74). Given such monopolies, the decisions made by these beef suppliers about the content in their food products impact heavily on the actual choices of the consumers (Patel 2007, pp. 12–14).

Choice as Capacity to Make Decisions

Within standard bioethics, a medical procedure must be consented to by the patient, and for this

consent to be meaningful, the patient must be properly informed about their choices. Similarly in consumption, an informed consent model of choice might be offered in which a person must know the content of their choice in order for that choice to be meaningful. This may then require that the consumer know the food type that they are consuming – its ingredients and various production methods. Kessler argues that breaking “sugars” down into multiple entries on a list of ingredients gives a false idea to the consumer of how much sugar they are consuming (Kessler 2009, p. 103).

On a similar informed consent line – where obesity is concerned – the consumer needs to properly understand the correlation between a given food option and obesity. Kessler argues that people don’t properly know what it is when they are eating (Kessler 2009, pp. 101–110). The recent development of “traffic light” systems on food packaging is one way of giving consumers access to easily recognizable indicators of a food’s content and its potential association with obesity (Egger and Swinburn 2010, p. 101).

A third way of conceptualizing consumer choice is whether the individual actively endorses their decisions. Brian Wansink describes a host of perceptual and environmental triggers that impact on food types, serving sizes, and consumption patterns (Wansink 2006). In a similar line of thought, Kessler argues that the sugar, fat, and salt content of processed foods, mentioned earlier, have the capacity to override people’s capacity for reflective decisions (Kessler 2009, p. 58–60). Rebecca Brown has argued that, in order for a consumer to be held properly responsible for their food decisions, they must not only be properly informed of the impact of their food choices but be able to reflectively endorse such decisions (Brown 2013). Many point out that given their limited cognitive capacity and limited social development, children are both unable to make properly informed decisions and to reflect upon these decisions (Pollan 2006, pp. 109–110; Roberts 2008, pp. 83, 105; Schlosser 2003, pp. 43–57).

Government Intervention in Food Choice

Given the costs individually, nationally, and globally, people argue that there is a governmental responsibility to intervene in the food choices made by consumers (Egger and Swinburn 2010, p. 35). There are, however, a range of different interventions that a government can make.

One intervention point is in the market, through changes to taxation and subsidies of obesity causing foods, such as the Danish tax on saturated fats, introduced in 2011, but removed in late 2012 BBC (2012). Paul Roberts and Michael Pollan have both argued that many fast food and highly processed foods are unnaturally cheap as a result of tax subsidies and government support of certain food types and production methods (Kersh and Morone 2002, pp. 150–151; Pollan 2006, pp. 200–201; Roberts 2008, pp. 135–136). In order to reduce obesity levels, they both argue, such subsidies should be reduced or removed, making processed foods more expensive and less accessible, and so reduce consumption.

In line with the informed consent model of consumption, many regions have particular food labeling requirements. As mentioned, common examples of this are the traffic light system or “calorific score” which some governments have made mandatory on all takeaway food, i.e., the New York City requirements for calorie labels on menus (Grynbaum 2012).

A key battleground revolves around advertising. Many writers and activists promote bans on advertising especially to children and to require more advertising of healthy choices. For instance, Schlosser discussed the US attempts to ban advertising fast foods to children in the early 1980s (Schlosser 2003, pp. 45–46) Gary Egger and Boyd Swinburn describe a similar attempt made in Australia in the early 2000s (Egger and Swinburn 2010, pp. 96–103). In reference to food availability, Schlosser describes attempts limit to the access of fast-food suppliers to vulnerable areas such as the provision of vending machines and fast-food distributors in schools (Schlosser 2003, pp. 51–57).

Rather than directly banning certain food types and distributors, Richard Thaler and Cass Sunstein describe what they call “liberal paternalistic interventions” to improve healthy choices. For instance, they argue that it is not necessary to constrain negative choices but to make healthy choices easier and more attractive. One example they cite is to make fresh fruit easier to reach than processed foods (Thaler and Sunstein 2009).

A more direct approach can involve directly prohibiting the sale of certain food types and/or distribution options. For instance, in 2012, New York City attempted to bring in a law that prohibited the sale of supersized soda serves. However, due to opposition, at the time of writing, this direct attempt at intervention in New York City was unsuccessful (Davies 2013; Olson 2013). The reasons for and against government intervention in consumer choice are discussed below.

Reasons for and Against Governmental Intervention via Consumer Choice

As many of these reasons have been mentioned already, this section will summarize reasons for government intervention in food choices. Firstly, given the role of consumption in individual health and given the aim to decrease individual burden of disease (also mentioned below), a government has a duty to protect individual’s health. Note that this is not a universal argument, as certain libertarian positions would restrict the role of government to the night watchman. Robert Nozick is perhaps the paradigm example of this position (Nozick 1974). Second is the increased burden on public health. Thirdly, reducing unnecessary consumption can lead to decreased used of arable land and water and may decrease pollution (Egger and Swinburn 2010; Patel 2007). Finally, due to the increased intensity of high-throughput food industry, some argue that obesity indirectly places a heavy burden on workers (Schlosser 2003, pp. 169–190) and animals (Singer and Mason 2006).

As mentioned, at the time of writing, New York City had failed in its attempt to introduce laws banning the sale of supersized soda serves (Davies 2013; Olson 2013). Given the reasons people give to reduce obesity, why would interventions be unsuccessful? There a set of related reasons that people raise against organized interventions in consumer choice, with governmental intervention seen as particularly problematic: individual freedom; personal responsibility; practical failure; and unfairness.

The first opposition comes from the idea of individual freedom. If freedom is about choices, then a reduction of options is a reduction of individual freedom. Any attempt to reduce the range of options available to consumers is unjustified governmental interference in individual liberty. For instance, Professor Russell Roberts states “The government should stay out of personal choices I make . . . My eating habits or yours don’t justify the government’s involvement in the kitchen” (Quoted in Kersh and Morone 2002, p. 142). Justice Tingle who ruled that the New York City ban on large-sized soda drinks saw the ban as “eviscerating” the separation of powers between elected officials and the unelected board who proposed the ban (Davies 2013).

Similarly founded in personal liberty, another set of reasons come from personal responsibility. This is derived, in part at least, from the idea that a person must endorse their choices for those choices to be meaningful. By reducing the set of options that a person can make, governmental interventions reduce the capacity for that individual to actively endorse their own choices. By making the government responsible for such choices, such interventions limit the individual from taking responsibility for their obesity. “A return to the discarded idea of changing individual behavior may be necessary. One way or another, the public . . . must be persuaded of a number of points. Whether or not they recognize their own role in it, they need to understand that obesity is a national health problem . . . Not just their own welfare is at stake” (Callahan 2013, p. 37). One proposal is to use social

stigmatization against obesity to motivate individuals away from obesity: “[y]et it is hard to imagine that much progress can occur toward solutions for obesity unless we bring some form of social pressure to bear against it” (Callahan 2013, p. 38). Such social disapproval is argued by some to be necessary for effective control of private behavior (Kersh and Morone 2002, pp. 143–144).

Another position against certain government interventions are the likelihood of failure. Daniel Callahan points to evidence various methods of reducing obesity, particularly simple individual dieting have been so far unsuccessful (Callahan 2013, pp. 35–36). One criticism of the New York City soda ban was that it was arbitrary and capricious, in that the ban only related to some drink types and not others (Olson 2013). A further set of reasons against such direct government interventions are that they unfairly place burdens on certain industries and food growers (Grynbaum 2012).

Summary

This entry describes the problem of obesity, characterizes different ways of conceptualizing obesity, and raises a series of causes for it. Looking at consumer choice as a key causal element in obesity, the entry surveys different aspects of consumer choice and then covers a series of arguments in support of and in opposition to government interventions into consumer choice as legitimate methods to control obesity.

Childhood obesity and responsibilities

Introduction

Obesity is defined by the WHO as “abnormal or excessive fat accumulation that may impair health.” It is a step beyond overweight, although the two are often addressed together: In practice, overweight and obesity are often defined by reference to body mass index (BMI), which is the weight of a person in kilograms, divided by the square of their height in meters. A BMI of over 25 is considered overweight, while a BMI over 30 is obese. As a measure of obesity, however, BMI has its critics, for reasons such as the fact that it does not distinguish between lean mass and fat mass and that it may not accurately account for the relevance of height differences.

The WHO estimates that obesity has nearly doubled worldwide since 1980; in 2008, 35% of adults were estimated to be overweight and 11% were obese. This problem has been particularly acute in the Western world: In the United States, over one third of adults are obese, while across the European Union, the figure varies between less than one tenth and almost a quarter. Childhood obesity rates are equally worrying: In Europe, approximately one fifth of children and adolescents are overweight; one third of these are obese. In the United States, roughly 17% of children and adolescents are obese.

Obesity is regarded as both an individual and social problem because it is associated with a number of health risks, such as diabetes, high blood pressure, heart disease, and some cancers. It gives rise to a number of ethical issues including responsibility for food choices, the role of the food industry, and public health advice. Obesity in children adds an extra dimension to the ethical issues. These include advertising to children but also intergenerational justice, in so far as concerns have been expressed that life expectancy may decline as a result of changes in the incidence of obesity. In relation to this group, however, it is arguably the case, more so than with other social groups, that the class of people buying and preparing food is not identical with those consuming it, making the identification of responsibilities, especially parental responsibilities, more complicated.

The range of courses of action available to counter obesity gives rise to ethical issues specific to each one: from attempts to “nudge” people into making particular choices, regulation of advertising, the role of the diet industry, functional foods, to gastric surgery as arguably the most extreme intervention. Celebrities increasingly are drawn upon to endorse particular courses of action, as in other sectors of the market. In addition to specific issues, however, some of which raise concerns about the extent of coercion involved, there are generic ones concerning stigmatization and discrimination.

Ten Have et al. (2011) have set out some of the ethical dilemmas associated with obesity interventions:

effects on physical health are uncertain or unfavourable; there are negative psychosocial consequences including uncertainty, fears and concerns, blaming and stigmatization and unjust discrimination; inequalities are aggravated; inadequate information is distributed; the social and cultural value of eating is disregarded; people's privacy is disrespected; the complexity of responsibilities regarding overweight is disregarded; and interventions infringe upon personal freedom regarding lifestyle choices and raising children, regarding freedom of private enterprise or regarding policy choices by schools and other organizations.

Value Judgments

One issue which needs to be addressed at the outset is the current prevalence of negative value judgments made about obesity. It cannot be taken for granted that the judgment that obesity is a bad thing is noncontroversial; widespread prejudice against obesity may be a result of social norms or aesthetic factors. It is well known that at different times and in different societies, a high weight has been or is a sign of social success or status. In the present context in Western societies, however, the opposite tends to be the case, with celebrity role models (with a few exceptions) being if anything underweight. This in itself gives rise to ethical issues, leading to concerns about young people developing eating disorders in the desire to be thin (see “► [Body Image, Gender, and Food](#)”).

There are thus costs associated with weight at either end of the spectrum, with lack of clarity about what is a desirable “norm” in the light of social context. At the very least, however, many people who are obese do not want to be (whether they would were it more socially acceptable is perhaps a question to be explored elsewhere).

Causes of Obesity

From one point of view, the cause of obesity appears simple: Where the intake of energy is not balanced by the expenditure of energy, over time this will result in excess weight and eventually obesity. This view appears to have been established firmly by the nineteenth century (Bray 1990). The picture is more complicated than that however: Causal factors involved in producing this imbalance are multiple and varied. The influence of different factors is frequently disputed, but it is broadly accepted that obesity results from the complex interplay of genetic, behavioral, and environmental factors. Gene-environment interactions, in particular, are believed to play an important part in explaining obesity, and much research is ongoing in this field at the time of writing.

Beyond consideration of the causes of obesity in general, special attention has recently been

focused on trying to explain the rapid rise in obesity rates across the world in the past 30 years. Although there is evidence to suggest that some people do have genetic factors that make it more difficult for them to lose weight, the overall change at a population level has occurred too fast to be explained by genetics, so examination of this issue has focused on possible ties between social change, the environment (including the “obesogenic environment”) and human diet.

The “obesogenic environment” hypothesis points to a complex matrix of factors which combine to make it harder for individuals to avoid obesity. Essentially, in certain areas, fast food has become ubiquitous, while exercise has been eliminated, for example, by the use of mechanized transport. The related idea of “food deserts” suggests that it has become impossible for the inhabitants of certain (predominantly urban) areas to access healthy food (see “► [Food Deserts](#)”).

Some accounts have attempted to place the blame on specific foods or ingredients, such as high fructose corn syrup. Others point to contaminants or toxins as being to blame: BPA, found in plastic bottles, for example; PCBs; PFOA; and tributyltin as cited by Guthman (2012). On the other hand, Lakdawalla et al. (2005) argue that obesity is a result of economic progress, relating to both falling relative food prices and a shift away from manual labor.

Discussion of possible causal explanations of obesity is important, as the purported causes of obesity tend to play a dominant role in ethical discourse surrounding the topic. This of course has implications for the allocation of responsibility – not just causal responsibility or blame, but responsibility or duty to act, by reducing levels of obesity or ameliorating the associated problems.

There is clearly much work to be done, however, in picking apart the causal factors implicated in obesity, as emerging research in the field of epigenetics points to enduring, transgenerational obesogenic effects of certain environmental factors. This might indicate additional parental or at least maternal responsibilities.

Responsibilities

In parallel with the simplest causal explanation being an imbalance between energy intake and energy expenditure, the default account of responsibility focuses on individual food choices. From this point of view, obesity is the result of freely made decisions by individuals (e.g., eating fast food instead of salad; driving instead of walking). It follows that the responsibility for dealing with the consequences of obesity should also rest with the individual: His or her food choices need to change (see “► [Ethical Assessment of Dieting, Weight Loss, and Weight Cycling](#)” and “► [Food and Choice](#)”).

There are at least two different types of problem with this kind of explanation: First, it ignores the *context* in which choices are made; second, it overlooks the *dimensions* of choice. Reflection on context shows the extent to which choices may be subject to external influences which cast doubt on the possibility of a “free” choice. Constraints range from availability of (varied) food, stress, sleep deprivation, time pressures for shopping and preparing, the costs of “healthy” choice, peer group pressure, and the influence of advertising.

Turning to the dimensions of the making of a choice itself, what is at issue here includes information and knowledge. Information about the constituents and calorific values of food is important. In spite of advances in food labeling, however, consumers know, from scandals such as that of horse meat passed off as beef, that what they read on a label is far from 100% reliable. Information on calories can also be misleading in so far as labeling overlooks facts about fiber and the difference in energy values between raw and cooked foods. It has to be acknowledged that some information relevant to food choice is quite complicated, such as the difference between different types of fat and between omega 3 and omega 6, and this situation is not helped by regular changes in publicly available dietary advice about whether food x or y is good or bad for you (see “► [Food Labeling](#)”).

Making a choice is not simply a matter of having relevant information. Those who give

prominence to the role of individual choice might see weakness of will as the main enemy of “healthy” informed choice. Information is also subject to interpretation, however, in the light of a person’s values and the type of person they see themselves as being. A choice to be a meat-eater, vegan, or vegetarian, for example, may be a significant aspect of a person’s identity. Stereotypes such as “Real men don’t eat quiche” may actually be internalized.

These aspects of an individual’s relationship with food are found more broadly in different food cultures. The slow food movement, for example, is likely to affect individual food choices in a different way from a culture that views food as basically fuel rather than a social bonding mechanism.

The allocation of responsibility to individual choice has been identified by Tsjalling Swierstra (2011) as one of a number of competing discourses. He labels it the behavior discourse. By contrast, the environment discourse, related to the obesogenic environment hypothesis discussed above, proposes that the numerous choices which lead to obesity are not in fact freely made, but are decided for us in large measure by the environment. If fast-food restaurants are the only food vendors around, and there are no footpaths to walk on, then we are bound to adopt unhealthy behaviors. Responsibility, both causal and moral, is therefore shifted to institutions that have the power to change the structural determinants of adiposity.

Swierstra’s final discourse, the body discourse, claims that obesity is primarily as a result of our body’s natural functioning. This discourse separates out causal and moral responsibility by ruling out the existence of a blameworthy actor. Internal genetic factors and the working of one’s metabolism may affect weight in ways that are beyond the individual’s control.

Obesity: Proposals for Action

Some have drawn attention to how the lack of clarity in regard to the causal relationships surrounding obesity may allow relevant actors to

avoid taking responsibility (Harris et al. 2009). It is common to describe causation in terms of a “chain” indicating that all that is needed to solve the problem is to find the weakest link and allocate responsibility accordingly. The mesh of interrelated factors leading to obesity does not appear fit well into this trope, and waiting for it to be untangled may delay action longer than is acceptable.

Therefore, in addition to causal responsibility, it is important to consider what can be done about the problems brought about by obesity and which actors may have the ability to mitigate any harms arising (Holm 2007; Kersh et al. 2011).

Individual Responsibility Revisited

Many see individual choice as the target here, with proposals ranging from coercion to persuasion and empowerment. The most draconian measure may be use of the taxation system to direct choice. Coercive measures are also possible within a health-care setting, with denial of treatment unless weight is lost. Justification may be given in terms of the reduced chances of successful treatment in the absence of weight loss. The aim of “empowering” individuals to make healthy choices was exemplified in the UK Department of Health’s White Paper *Choosing Health* (2004). This strategy depends on the view that individuals can and will make healthy choices if they are given appropriate information.

Taxes intended to reduce obesity may not only hit the poorest hardest but also have a side effect of increasing malnutrition. The work of Thaler and Sunstein has highlighted a number of problems with the individual responsibility paradigm. Mindful of the threat to personal autonomy of restricting choice, they propose a less intrusive method of regulatory involvement, relying on the “nudge” (Thaler and Sunstein 2008). Measures could include rearranging how options are displayed in food outlets and ensuring that people are given a minimum level of information (see “► Grocery Store Design”).

These considerations raise the question of what the proper role of government is in this area. This is relevant not only to the issues around individual choice but also to effects on the potentially

obesogenic environment. From a neoliberal perspective, the role of government in relation to food is simply to ensure food safety and to facilitate the provision of information to individuals on which they can base their choices. In this regard, the regulations surrounding food tend to be different from those affecting drugs, where both safety and efficacy are an issue (although the dividing line between food and drugs is not completely clear-cut).

Regulation of safety has to have regard to particular subgroups of the population, e.g., children and pregnant women, and regulation of advertising to children might be regarded as an aspect of its safety remit, in so far as pushing “unhealthy” foods onto children might cause actual harm.

There are, of course, competing interpretations of what the proper role of government *should* be, from different philosophical viewpoints. In so far as government tries to affect food choice beyond ensuring safety, it might be regarded as unduly paternalistic. In contrast to the neoliberal vision, however, a position that has a concept of the common good to be pursued might argue that the role should encompass more than safety and the promotion of certain values, such as social justice. This might lead, for example, to the facilitation of certain lifestyle choices, including fairness regarding food styles (Korthals 2001).

At the time of writing, it seems that concerns about obesity are trumping other considerations, whether this is construed as part of a broadly understood safety remit or through consideration of social and economic costs. The scope for action of government is also, however, affected by competing economic and political interests, such as the protection of the food industry as a key player in the economy of a modern society.

The Food Industry

The food industry plays an important role in relation to obesity. It has been a leading driver in the changing food environment, from the increasing prevalence of fast food and ready meals to the use of pesticides. Despite the nominal freedom of individuals in deciding what they eat, the food industry plays a crucial role in creating the

structure within which individuals must make their choices.

Food Marketing

The role played by marketing in setting the tone for what people eat may be a particularly relevant justification for imposing some level of responsibility on this sector. Despite the ideal of perfectly rational consumers making informed choices, consumers are often swayed by what may be perceived as irrelevant factors. Marketing has the power to affect consumer choice not only by providing or withholding information about products but by how the information is packaged and at which consumers the information is targeted. The role of food marketing in defining consumer perceptions of food “healthiness” is also important to consider. What once may have been purely within the realm of public health authorities has been encroached upon gradually by ubiquitous marketing campaigns emphasizing the benefits of one food or another.

In particular, the way that food is marketed to groups who may be particularly susceptible to manipulation, such as children and those in developing countries, may raise some concerns (Harris et al. 2009; Witkowski 2007). The makers of fast food and sweetened drinks have been especially astute in targeting these two groups.

In some countries, regulators have taken action to limit advertising aimed at children for these reasons. Advertisers may be precluded from advertising certain classes of food completely or at certain times of day. The possibility of such regulations being introduced may act to bring about more responsible behavior by the food industry (see “► [School Lunch and Gender](#)”).

Corporate Social Responsibility

Corporate social responsibility (CSR) has emerged in the last 60 years as an acknowledgement of the impact of corporations on society and the potential for corporations to make their impact positive. In the food industry, CSR has come to the fore as issues such as the use of genetically modified crops, animal welfare, and the treatment of workers have been prominent topics of debate (Maloni and Brown 2006).

In the wake of a series of popular critiques of the role of the food industry in relation to obesity, some firms have sought to improve their image by taking some steps to address it. This has included not only promoting the health benefits of their products but also trying to make their products healthier, for example, through the increasing use of whole grains, and to encourage individuals to make healthy choices by providing information and promoting physical activity or voluntarily assuming some responsibility by undertaking to decrease obesity rates (Herrick 2009).

There are numerous examples of this in action, from recent moves to project a healthier image and to be seen to empower consumers by companies such as Coca-Cola and McDonalds, to the sponsorship of physical activities for children or the voluntary reduction in fat levels in some products.

There has, however, been some criticism of these strategies. It is unclear what merit there is in some of the health claims made by companies, especially where these claims stem from only one aspect of the product. Encouraging individuals to make healthy choices may be seen as merely trying to shift blame for obesity away from food and the food industry (Herrick 2009) (see “► [Corporate Social Responsibility and Food](#)”).

Functional Foods

When changing the products is seen as an alternative to manipulating choice, this might be regarded as a “technical fix,” looking for opportunities for products that counteract obesity because of their effects on the body, such as “functional foods” (Choudhary and Grover 2012). These are not the same as “miracle diet” products. The constant search for the quick-result diet has been a phenomenon of long standing, but the consensus of opinion is that long-term lifestyle change is necessary to counteract obesity. Manufacturers of functional foods focus on ingredients which are part of a normal healthy diet (such as chillies) but around which products can be made which may speed up metabolism or reduce hunger (Chadwick et al. 2003). This might be seen as less of a *responsibility* for the food industry, rather more of a *marketing opportunity* (see “► [Functional Foods](#)”).

Epigenetics

Beyond the possibility of a technical fix, recent advances in our understanding of epigenetics have suggested that science may have important new insights to offer in this field. Although genetics does not have the complete answer to why some people become fat and others do not, there are genetic factors implicated in obesity, and these may be triggered, or not, by environmental factors. Epigenetics examines factors over and above the genome that may affect gene expression and understands the influence of environment to be far beyond the obesogenic environment hypothesis. Significant factors may relate even to maternal behavior prenatally. It remains to be seen what the implications of this rapidly developing science will be. It has the potential for opening up a new area for thinking about responsibility in relation to obesity, if parents are considered responsible for behavior during pregnancy and early childhood which might affect the propensity to obesity in their children (Chadwick and O'Connor 2013).

Parental Responsibility

The question of parental responsibility for obesity in relation to their children is multifaceted, and it is not possible to explore every aspect of it here. Parents have a significant influence over not only what their children eat and what physical activity they are involved in while they are young (and the degree of influence will vary greatly with the age of the children), but over the attitudes of their children towards food and exercise later in life (Holm 2008; Perryman 2011). Because of this, it may be considered appropriate to impose some responsibility for childhood obesity on parents.

It is important to remember, however, not to overstate this. While women during pregnancy are already expected to limit consumption of alcohol, for example, in general obesity fits uncomfortably into the broader scheme of parental responsibility. Generally, parents are allowed a high degree of freedom in choosing how to bring up their children (although parenting decisions are often – at least morally if not legally – required to be made in the best interests of the child). It may only be thought permissible to impose particular duties on parents where there is a clear, objective risk of

harm to children. Given the uncertain and primarily distant nature of the health risks attached to obesity, and the subjective nature of some value judgments surrounding obesity, it may be inconsistent with the freedom of conscience allowed to parents to curtail their range of choices.

Summary

Obesity is a complex moral issue: It is clear that there are health problems associated with it, and yet much of what people think about obesity is clearly motivated by subjective aesthetics or prejudice. It is also apparent that although we can identify a number of factors which are causally linked to obesity, food intake, exercise, genetics, and environment, how these factors work together has yet to be established.

Against this background, a number of debates have developed: whether obesity should be treated as an individual failing, as a result of environmental factors or genetically predetermined; whether responsibility for dealing with the "obesity epidemic" should fall to individuals, governments, or the food industry; and even about whether obesity should be seen in a positive, negative, or neutral light.

Occupational Risks in Agriculture

Sven Ove Hansson

Division of Philosophy, Royal Institute of Technology, Stockholm and Swedish University of Agricultural Sciences, Uppsala, Sweden

Synonyms

Accidents in agriculture; Health and safety; Workplace risks

Introduction

In literature and the visual arts, the very notion of an idyll means a depiction of rural life, describing life and work on a farm as healthy, gratifying, and in harmony with nature. Children's books, in particular, abound with rustic idylls where children play freely, undisturbed by the dangers of modern life.

Real farmwork was, and still is, very dissimilar from these representations. Agriculture is more dangerous than most other occupations. Old hazards like sickles and bolting horses may have become less common, but they have been replaced by new ones such as pesticides and tractor rollovers (ILO 2010).

A third of the world's labor force works in agriculture. In the richer countries, only around 2–3% of the workforce work on farms, most of them on highly mechanized farms. In poor countries, more than half of the workforce work in agriculture. About 40% of the world's farmers and agricultural workers are women (ILO 2012, p. 99). Child labor is more common in agriculture than in any other economic sector. 130 million children, about 60% of the world's child laborers, work in agriculture (Diallo et al. 2010, p. 13).

Agriculture is a particularly hazardous occupation in both industrialized and developing countries. In countries with well-functioning statistics, the death rate due to occupational accidents in agriculture is usually at least twice as high as the national average, and agriculture is one of the sectors with the highest death toll. According to ILO estimates, at least 170,000 agricultural workers are killed in workplace accidents each year (ILO 2009). This figure is uncertain since reporting of accidents and occupational disease in agriculture is often highly incomplete, in particular in third world countries.

Accidents

Some of the causes of agricultural accidents have been with us since ancient times. *Domestic animals* can kick, bite, knock down or step on a worker, or press her against a wall or a fence, sometimes with fatal outcome. The risk is enhanced when the animal is agitated or panicking and when the worker and the animal are inside the same tight workspace such as a small stall or pen. Humane treatment of animals reduces the risk of dangerous behaviors. Barns and collection chutes can be constructed to separate workers from animals. Milking, immunization, trimming of hooves, and other operations that require close contact with the animal can be performed in containment facilities that protect the worker against kicking and biting.

In tropical and subtropical areas, *wild animals* are major causes of occupational accidents. Large mammals that look for food in the farmland can be dangerous, in particular when one tries to drive them away. In Africa, the hippopotamus is particularly dangerous for farmworkers. Snakebites are also common in tropical areas.

In mechanized agriculture, *tractors* cause a large number of injuries. In many industrialized countries, a majority of the fatalities in agriculture are due to tractor accidents. Rollover accidents are the most common type. It is also common for workers standing behind a tractor to be run over when it is reversed. The risk of accidents can be reduced by educating drivers, keeping bystanders

and in particular children away, and avoiding driving on slopes. Safety equipment such as seat belts and protective frames (roll over protection structures, ROPS) substantially decrease the risk for drivers.

A wide variety of *other machines* contribute to making farming a dangerous occupation. Machines containing accessible moving parts and cutting edges can cause cuts, fractures, amputations, and crushings with disabling or fatal consequences. Harvesters are among the most dangerous of these machines. Many accidents occur when clearing blockages or performing maintenance or repairs. In the third world, *hand tools* such as machetes used for cutting sugar canes cause many serious cutting wounds.

Fall accidents are common on farms, resulting for instance from poorly maintained stairs and ladders and from work on roofs, silos, or the top of vehicles without protective equipment. *Traffic accidents* are common when rural workers travel between fields for instance on trucks. *Electric accidents* and *fires* are other causes of accidents in agriculture.

Occupational Diseases

Diseases caused by biological material have a long history in agricultural production. The inhalation of *dusts from grains and other plant material* can give rise to respiratory diseases. The smallest particles (less than .005 mm) go unnoticed since they cause no immediate irritation but they are the most dangerous ones since they penetrate into the alveoli, the small sacs that are the terminal ends of the branching tree of pulmonary ducts. Many types of bioorganic dust can give rise to inflammatory diseases of the lung. Probably the most common of these are farmer's lung (moldy hay) and byssinosis (cotton dust). Others are bagassosis (moldy molasses), coffee worker's lung (coffee bean dust), malt worker's lung (moldy barley), tobacco worker's lung (moldy tobacco), and winegrower's lung (moldy grapes). The so-called hay fever is an allergic reaction to grass pollens that tend to be prevalent at the time when hay is being harvested. The risk

of these diseases can be substantially decreased if adequate measures are taken to decrease exposure.

Gases formed during crop storage can also be toxic. Silo-filler's disease is a dangerous acute condition resulting from inhalation of nitrogen dioxide formed from fresh silage. Work inside a grain storage facility is also associated with other dangers such as grain dust explosions and suffocation due to lack of oxygen or engulfment in avalanching grain. Grain storage bins should never be entered without careful protective measures including a body harness with a lifeline or a boatswain's chair.

Dust from domestic animals, usually from dander (particles of shed skin and fur), can give rise to allergic rhinitis. Dust from droppings and feathers of birds give rise to bird fancier's lung (bird-breeder's lung), a serious and potentially fatal form of allergic lung disease.

In large-scale, high-density animal production, workers can be exposed to high concentrations of *gases from animals*, arising from flatulence and from the decomposition of urine and fecal matter. Important such gases are methane, ammonia, and hydrogen sulfide. Ammonia and hydrogen sulfide both give rise to irritation of the eyes and nose. Hydrogen sulfide is a treacherous gas since its smell of rotten egg disappears at the higher concentrations that are acutely fatal. Hydrogen sulfide from slurry pits has caused many deaths.

In livestock production, farmworkers can be affected by various *zoonoses*, i.e., infections transmittable from animals to humans. Some of the most well known of these are summarized in Table 1.

Farmworkers can also contract *zoonoses from nondomestic animals*. Contacts with snail-infested water, for instance, in rice fields, can give rise to schistosomiasis (bilharzia), a disease caused by a parasitic worm carried by snails. Barefoot walking and lack of sanitation contribute to the risk of hookworm infection that is a major public health problem in particular in Africa and Asia. Bites and stings from spiders such as ticks, scorpions, and in particular insects such as mosquitoes, flies, and fleas are other major causes of disease.

Occupational Risks in Agriculture, Table 1 Some major zoonoses, i.e., infections that are transmitted from animals to humans

Anthrax	A bacterial disease that spreads by spores. Cattle and other herbivorous mammals can contract it through ingestion of the spores while grazing. It spreads to humans through contact with diseased animals or consumption of flesh from them. The disease has high mortality
Bovine tuberculosis	A form of tuberculosis that is usually transmitted through unpasteurized milk or through contact with infected animals. In areas where milk is not pasteurized, it is a common source of tuberculosis in humans
Brucellosis	A bacterial fever disease that is transmitted from cattle through unpasteurized milk or infected tissues such as placentas
Campylobacteriosis	A bacterial disease that causes diarrhea and fever. It is usually transmitted through unpasteurized milk or contact with infected poultry or livestock
Cryptosporidiosis	A disease caused by a protozoon (single-celled organism) that gives rise to diarrhea in humans. It can be contracted through feces from infected cattle or water that has been contaminated with such feces
Leptospirosis	A bacterial disease with symptoms such as fever and diarrhea. It is commonly transmitted to humans from animal urine via contaminated water
Psittacosis (parrot fever)	A form of bacterial pneumonia that is spread by droppings from parrots but also from other birds such as hen and duck
Q fever	A bacterial disease that is transferred to humans from milk, urine, feces, amniotic fluid, or placenta from infected cattle and other domestic animals
Rabies	A life-threatening viral brain infection that is almost always contracted through bites from infected dogs. It kills more about 55,000 persons every year, 95% of them in Africa and Asia. Preventive vaccinations of both dogs and humans are efficient means to prevent the disease

Malaria kills more than 600,000 persons each year, about 97% of them in Africa (WHO 2011). The impacts of agricultural practices on malaria incidence are complex. In some areas, increased irrigation has created stagnant waters that augment mosquito breeding and therefore increase the risk of malaria. On the other hand, higher prevalence of cattle in developing areas seems to decrease the risk of malaria since the mosquitoes tend to feed on blood from cattle rather than humans.

Most zoonoses can be efficiently controlled with proper preventive measures such as animal vaccination, human vaccination, sanitation, and safe disposal of animal waste. Due to the lack of such measures, zoonoses are a much heavier burden on farmworkers in developing than in industrialized countries.

Pesticides are by far the most serious toxic risks in agriculture. Pesticides are divided into groups according to their targets. The most important of these groups are herbicides (against unwanted plants), insecticides (against unwanted insects), fungicides (against unwanted fungi), and rodenticides (against unwanted rodents). As a

rough rule of thumb, insecticides and rodenticides tend to be more dangerous to humans than most herbicides and fungicides. The majority of acute pesticide poisonings involve insecticides. Due to the prevalence of pest insects in tropical and subtropical climates, insecticides have a larger role in third world countries than in industrial ones where their use is also better controlled.

For most pesticides the dominant route of entry into the body is skin penetration. Mixing and loading of pesticides often leads to massive exposure of the hands and arms. Manual spraying that is standard in third world countries also leads to substantial skin exposure, in particular as it is often performed with leaking and otherwise deficient equipment. The legs of farmworkers are often exposed to pesticides from recently treated plant surfaces.

The other two routes of entry are inhalation and ingestion. Inhalation is often substantial for workers performing hand spraying. In addition, wind drift leads to inhalation by people in the vicinity, including children. Ingestion is often the result of insufficient hygiene, such as when food is eaten or cigarettes smoked with contaminated hands.

The symptoms of poisoning are different for different pesticides. Common acute symptoms are headache, skin irritation, and flu-like respiratory symptoms. High doses can be fatal. Some pesticides give rise to chronic poisoning, and some have been shown to be associated with cancer.

Due to lack of reporting routines in the most affected countries, the number of pesticide poisonings is extremely difficult to estimate (Litchfield 2005). The International Labour Organization (ILO) and the World Health Organization have made quite different estimates. The ILO estimates that about 17,000 (unintentional) fatal poisonings with pesticides take place each year, comprising 10% of the fatalities in the agricultural sector. The WHO estimates around 40,000 such fatalities annually (Rice 2000).

In addition to their implication in occupational fatalities, pesticides are also death-bringing in another way, namely, through suicides. Pesticides are the dominant means of suicide in many third world countries, and globally they are the most common suicide method. It has been estimated that around 300,000 suicides with pesticides are committed every year (Gunnell et al. 2007). Most of these suicides have a strong impulsive component, and there are strong reasons to believe that reduced access to highly lethal pesticides would lead to a substantial decrease in the number of suicides (Eddleston et al. 2006). (It has been hypothesized that by causing depression, occupational poisoning with organophosphate pesticides may increase the risk of suicides. That has not been scientifically substantiated.)

Agricultural workers are also affected by several *climate-related diseases*. In particular in tropical areas, the combination of high temperatures, high ambient humidity, and hard physical labor can lead to heat stress and heat stroke. Lack of drinking water further increases the risk of heat stress. In the same areas, exposure to ultraviolet sunlight increases the risk of skin cancer and cataracts.

Musculoskeletal disorders such as back pain and arthritis are common among farmworkers and may be associated with hard physical labor. Prolonged exposure to *vibrations* from tractors and other machinery gives rise to the hand-arm

vibration syndrome that is characterized by numbness and temporary loss of feeling in the fingers, in serious cases loss of dexterity and strength. Exposure to vibration is also associated with increased risk of spinal disk herniation and myocardial infarction.

Noise from animals, in particular, in swine confinement buildings, can reach levels that give rise to hearing loss. The same applies to noise from tractors and machines such as chainsaws and grain dryers.

Ethical Issues and Challenges

Agriculture differs from other sectors of the labor market in ways that have ethical implications for health and safety work. In this section some of these implications will be summarized in the form of five challenges for agricultural health and safety.

To a large extent, farmwork is performed by self-employed farmers. In many countries farmers are among the most underprivileged laborers, but they seldom form organizations like trade unions or take part in coordinated, collective activities. When an industrial worker is exposed to unacceptable working conditions, there is a factory owner who can be required to pay for the necessary improvements. When a self-employed farmer is subject to similar conditions, there is no one else than the farmer who is expected to pay, and often his or her means do not suffice to cover the costs.

If the government or an independent organization demands improvements in the working conditions of an industrial worker, then these demands cannot be accused of being paternalistic. The improvements will have to be made by the employer, who is then required to change the working conditions of others, not himself. In contrast, demands to improve the working conditions on small farms can be labeled as paternalistic; such demands interfere in the farmer's decisions on his own working conditions and they do so for his own good.

The difference is not quite as sharp as it was now presented. There are cases of paternalism in health and safety work in large industries. The

best example of this is demands that workers use personal protective equipment; it is primarily for their own sake that government agencies and – often – the employer require them to do so. There are also cases when health and safety measures by a self-employed farmer have a justification that goes beyond his or her own interests. One example is vaccination of cattle against zoonoses. By vaccinating his or her own herd, the farmer contributes to decreasing the risk for colleagues to be affected by the diseases in question. But in spite of these exceptions, health and safety work encounters the problem of paternalism much more often in agriculture than in other sectors. *The first challenge is therefore to find ways to prevent accidents and occupational diseases no less efficiently in agriculture than in other sectors, while respecting the special situation of self-employed farmers.*

Throughout the world, agriculture still tends to be a family business to a much larger extent than other ways to make a living. The limit between a private household and the same family's farm is less clear than the corresponding limit in other small companies. As a consequence the distinction between family relations and labor relations is similarly unclear. This may seem idyllic, but it means, for instance, that if the wife of a traditional farmer has a subjugated role, then she is dominated by the same man both at work and at home – doubly oppressed but in a single relation.

Probably largely because of the family-based organization, the role of women as agricultural workers has often been neglected even by health and safety authorities. Tools, machines, workstations, and equipment have been constructed to suit the male worker. It has not been a priority to make working conditions compatible with pregnancy and breastfeeding. Day-care facilities are seldom available, in spite of being the only practicable way to keep children away from the dangerous production areas where their mothers work. In summary, the traditional view of agriculture as a family business led by a man has made female farmworkers and their working conditions next to invisible. *The second challenge is to give the same weight to the interests of female and male farmworkers in spite of*

strongly entrenched traditions that keep women in a subordinate position.

Most farms are both a home and a workplace, with no clear line between the two functions. Therefore, children who grow up on farms grow up in a workplace. This has at least two important consequences. First, they are exposed to the dangers of the workplace. Kicking, biting, and bolting animals; infectious diseases spread by the same animals; insects spreading other diseases; reversing or overturning tractors, harvesters, and other cutting machines; dangerous hand tools; slurry pits with their dangerous gases and the risk of drowning; equally perilous grain storage bins; and not least pesticides – all these workplace dangers are also dangers to the children who grow up on farms. From the viewpoint of preventive health, it is regrettable that some of the most accident-ridden workplaces, namely, farms, are also the only workplaces that are the homes of hundreds of millions of children.
